more than two thirds as a maximum and more likely only one half. Granting, however, that there was not an Indian in the state escaping the survey, and comparing the seventy-three live diabetic Indians with the two reported dying each year with diabetes, one is driven to conclude that the duration of life of a diabetic Indian in Arizona is thirty-five years or that death certificates for Indians are faulty and fail to include the word "diabetes" where it belongs as a primary or secondary cause. Furthermore, the number of Indians with diabetes in Arizona compared with the total number of diabetic patients in the state bears essentially

5. Salsbury, C. G.: Disease Incidence Among the Navajos, Southwest. Med. 21: 230-233 (July) 1937.

the same relative proportion, 10 per cent, as do Indians to the total population. Diabetes in Arizona is just as common among Indians as among the rest of the population.

If the survey covered only two thirds of the Indians, the number with the disease would be raised from

seventy-three to 109, and the duration of diabetes in an Arizona Indian would jump to fifty-four years, which of course is absurd. A physician long associated with work among the Navajos replied to my question "What percentage of Navajos in Arizona ever see or come under the influence of a doctor?" "From 50 to 60 per cent," and to another question, "For what percentage of deaths do you suppose there is really known an accurate cause?" he answered "In our area my guess would be in about 25 per cent; in the back stretches of the reservation a much smaller percentage." Comparing these statements with the two annual deaths reported for the whole state yearly, the inference is clear that death certificates are lacking in accuracy. In fact, for the state as a whole the number of certificates filed "cause of death unknown" exceeds by several times those returned with the diagnosis of diabetes.

Doubting Thomases may say that the Indians had glycosuria but not diabetes. To this I reply that, of the first twelve blood samples sent to the Phoenix Pathological Laboratory from one of the Indian reservations because of suspected diabetes, eleven of the twelve showed hyperglycemia. Again I wish to give credit to

the liberality of that laboratory in making these and many other tests for me at so minimal a sum, at what I like to call "wholesale rates." It represents another example of the "fecundity of the aggregation."

The distribution of Indians by tribes is shown in table 5 and by age in table 6. I would point out that the Navajos are nomads and the Apaches herdsman, and the Pimas depend on agriculture and I understand harvest their crops on shares, allowing the Papagos to do most of the work.

DIABETES AMONG PHYSICIANS IN ARIZONA AND RHODE ISLAND

If diabetic mortality statistics are even an approximately accurate index of the incidence of diabetes in a community, one would expect this to be reflected in the incidence of diabetes among physicians. Therefore an investigation of diabetes occurring in doctors was made in Arizona and later, to test the validity of the comparison of its low diabetic mortality of 10 per hundred thousand with that of 42 in Rhode Island, or as adjusted for the two states for age and sex, 13 and 37, a similar survey was carried out in exactly the same way and among the same number of doctors in Rhode Island. If diabetes is one fourth or one half as frequent in Arizona as in Rhode Island, the signed testimonies of the physicians in these states do not show it. The results were practically identical. In each state requests were sent to 562 doctors, and to those who did not reply to the first request a subsequent letter was forwarded. Three hundred and thirty-nine doctors reported in Arizona and of these there were eight with diabetes, or a ratio of one diabetic doctor to forty-two nondiabetic doctors. In Rhode Island the responses were somewhat more liberal. In all, 392

physicians have so far reported and eleven stated that they had diabetes, making a ratio of one to thirty-six. The average age of the doctors reporting no diabetes in Arizona was 47 years and in Rhode Island 49 years, whereas the average age of those with diabetes in Arizona was 62 and in Rhode Island 61 years. Diabetes does not spare doctors in Arizona.

An estimate of the morbidity of diabetes among physicians in the United States can be made by a study of the deaths from the disease as reported by the American Medical Association.⁶ These amounted to ninety-one for the year 1939. The total number of doctors in the country at that time was stated to be 169,682. There was, therefore, one death of a doctor with diabetes for each 1,891 physicians. If we assume that the duration of the diabetes among doctors is ten years, then the number of physicians living in the United States with diabetes would be one in 189. If we further assume a duration of twenty years, it would be reduced to one in ninety-four. Therefore, among the 562 doctors in Arizona one would expect three with diabetes on the basis that doctors lived ten years or six with diabetes if they lived twenty years. As a matter of fact, eight doctors were found in Arizona with diabetes, or one diabetic doctor for every forty-two physicians, or fully up to expectations. Of course, I am dealing with small numbers.

DIABETES AMONG CLERGYMEN IN ARIZONA

Doctors and ministers in Arizona are approximately equal in number. Curiosity led me to attempt a survey of the incidence of diabetes among the clergy. The replies were far less numerous. Thus, of 531 clergymen only eighty-eight responded, and only two of these

stated that they had diabetes, a ratio of one to forty-four. However, other methods of investigation disclosed three more ministers with diabetes, so that finally the ratio of diabetes among ministers replying was one in forty-four, but of all those investigated was five or one for each 106 ministers, if it is assumed that we had reports for each one of the ministers in the state. The ages of the ministers I do not know.

DIABETES AMONG PRISONERS

The investigation of diabetes among the Indians in Arizona was handicapped because of their inaccessibility. The density of population on the Navajo reservation is only about 1.5 Indians to a square mile. Even with an automobile, hunting diabetic Navajo Indians is a rather exhausting sport, and to give myself a brief respite I turned to two areas where the task would be easier and there would be no worry that any person with diabetes would escape the Benedict test. In Florence is an institution admirably adapted for the purpose, and the state prison there furnished me with some 800 subjects. My preliminary inquiry was disappointing, but the superintendent and the prison physician were so cooperative that now I have the privilege of reporting that in the state prison at Florence where one diabetic individual was expected by National Health Survey tabulations, three were found, a higher percentage than on Riker's Island in New York. Just why diabetes appears more frequently among prisoners in Arizona than in New York I cannot say. At any rate I can report that the blood sugar tests of the three diabetic prisoners, as made at the Phoenix Pathological Laboratory, showed 342 mg., 458 mg. and 368 mg. respectively. The ages of the diabetic prisoners ran true to form. The average age for the diabetic prisoners was 46.6 years. Furthermore, obesity ruled among the diabetic in the Arizona State Prison just as it does in Boston. The average weight for all the prisoners was 152 pounds (69 Kg.), but the average weight of the diabetic prisoners was 194 pounds (88 Kg.). If prisoners weigh so much in Arizona, the question arises as to what the weights are for citizens of Arizona. It would be desirable to secure weights of Indians, particularly the Navajos and Pimas.

DIABETES AMONG THE INSANE

The state mental hospital in Phoenix furnished another group where one could be sure that tests for diabetes were performed on all inmates. The search for diabetic patients revealed that among an approximate thousand inmates there were fourteen with diabetes instead of the six expected. For comparison are available figures for the 26,031 mental patients in Massachusetts, among whom 219 were diabetic, or a ratio of 8 per 10,000. In other words, diabetes among the prisoners and insane in Arizona ranks high and apparently fully as high as if not higher than in similar populations in New York and Massachusetts.

TOTAL NUMBER OF DIABETIC PERSONS IN ARIZONA

The survey disclosed 755 diabetic persons in Arizona. The distribution by sex was as expected: males 358 and females 397. The age distribution was the same as that for other areas and is shown in table 8.

The crux of the situation, however, is to determine what percentage of the inhabitants of the state was covered by the survey; that I do not know, but it has been variously estimated from a low of 40 per cent for Mexicans to a high of 75 per cent for the white population. The census of 1940 will be helpful and, in fact, essential in this regard. I do not wish to enter into a detailed discussion of the various methods that could be employed to enable one to compare the morbidity incidence of Arizona for diabetes with that in other sections of the country in order to test the reliability of its mortality statistics. However, I will briefly enumerate some of them.

The number of diabetic persons in Massachusetts has been a subject of close study for many years. It was here that the first field work was done on chronic disease and therefrom certain conclusions could be drawn. Dr. Lombard and I also investigated the death certificates of 744 diabetic patients previously treated by me and found that only 62.9 per cent were so classified on the death records. Even if all had had the word "diabetes" on the death certificate only 82.5 per cent of the total number would have been thus classified by the joint causes of death. Thus the mortality from

diabetes as recorded in the death records represents about two thirds of the mortality of persons with the disease and four fifths of the true mortality as measured by the joint causes of death.

During the last eleven years, beginning in 1929, in Arizona there have been 438 recorded deaths from diabetes, the low figure occurring in 1934 and the high figure in 1939. That makes an average of forty deaths a year. If it is assumed that this figure, as in Massachusetts, represents only 62.9 per cent of the deaths,

the total number of persons dying in the state with diabetes would have averaged for this period sixty-four annually. If this figure is multiplied by ten as a fair estimate for the duration of diabetes, the expected number of diabetic persons in the state would be 640, but this number is based on the whole state whereas the survey showed 755 deaths for a part of the state.

In determining the extent of the state covered, one might base it on the number of physicians reporting diabetes or no diabetes as compared with the total number of physicians, which this February in Arizona I thought, from all I could learn, to be 562. Furthermore, this proportion would be 290/562 and for the

* Rates based on 1937 population; no estimate made for 1938.

whole state the number of persons with diabetes would be raised from 755 in the survey to 1,471. Objections may be made that the physicians not reporting at all may have more or less diabetic patients than those reporting. The answer to that no one can give.

The number of diabetic persons in Massachusetts has been most carefully estimated and if the number 17,500 is divided by the number of physicians practicing in Massachusetts, 7,528, the number of patients reported by each physician. If this same method is applied to the 290 physicians reporting 755 diabetic patients, there are 2.6 per physician in Arizona.

Still another method is available, namely to assign to the state the expected number of diabetic persons based on the National Health Survey and at the same time with arbitrary allowances for coverage for the various types of population. For this special calculation I am indebted to Mr. Marks.

The calculation shows that for all groups save Mexicans, and the indications are that the Mexican population has decreased appreciably since 1930, the percentage ratio cases reported to those expected in the population surveyed met the requirements at both the lowest and the highest estimations of coverage.

Of far greater significance in my own mind than these various estimations are the following two letters of approval which I have received respectively from Dr. Lombard, and Dr. Dublin and Mr. Marks.

At the present time when the available census records are ten years old it is impossible to compute either morbidity or mortality rates with any assurance that they will be reasonably accurate. However, from a careful study of the morbidity data collected by Dr. Joslin and applying to an estimated population of both Arizona and Massachusetts the age specific diabetes morbidity rate obtained in the National Health Survey, an expected number of the cases was such that I am strongly inclined of the opinion that diabetes morbidity does not vary greatly in this country. Mortality does vary and a logical explanation of this would be that for some reason or other many individuals dying with diabetes are not so certified on their death certificates.

HERBERT L. LOMBARD, M.D., Boston.

Low recorded death rates from diabetes, as in Arizona, which you chose for your survey, must not be accepted at their face value. Factors such as age, sex and racial composition of the population, the density of population, economic status, and the number and location of doctors and hospitals all influence the recorded mortality. Thus, it is known that the mere adjustment of death rates to a common sex-age basis reduces appreciably the margin between the diabetes death rates in a state like Arizona and those which have high reported death rates. The rates in Arizona's cities are of the same order of size as those elsewhere in the country. Furthermore, your survey has shown an incidence of diabetes, based on actually reported cases, which after suitable allowance for her low proportion of old people and her high ratio of males to females, very much closer to the average for the country than is found in the mortality data. For the population of the state as a whole, and for the various groups by sex, age and race, the numbers of reported cases approximate, within reasonable limits, the numbers one would expect to find in comparison with the general prevalence of diabetes.

LOUIS I. DUBLIN, Ph.D., and
HERBERT H. MARKS, New York.

June 11, 1940.

CONCLUSIONS

In Arizona the reported diabetic mortality is not consistent with diabetic morbidity. A survey of persons with diabetes in the state conducted by Arizona physicians and myself, granting a reasonable allowance for the number of persons covered in the survey, makes it evident that the incidence of diabetic morbidity in Arizona is comparable to that of the National Health Survey. This held true for all groups including Jews, physicians, ministers, prisoners, the insane, males and females, the white population and the Indian population. Among the Mexican population there was a deficit, as the number of persons with diabetes found was less than the theoretical number expected, for which the explanation may be inaccuracy of population data. Final calculations based on the number of persons with diabetes in Arizona must await the completion of the 1940 census.

A diabetic survey in Arizona supports the thesis that diabetes is universal and conforms to the rule that the incidence of diabetes is highest where (1) the average age is the greatest, (2) women predominate, (3) obesity is most frequent, (4) the proportion of Jews is greatest, (5) medical supervision is closest and (6) deaths are most accurately reported.

PREDICTION AND PREVENTION OF
PREGNANCY ACCIDENTS IN
DIABETES

PRISCILLA WHITE, M.D.

AND

HAZEL HUNT, A.B.

BOSTON

Our present conception of the mechanism of the accidents in diabetic pregnancies has been the outcome, first, of our realization that adequate dietary control of diabetes and insulin therapy did not lower the fetal mortality rate and, second, our correlation of the behavior of diabetic pregnancies in relation to the balance of pregnancy hormones—chorionic gonadotropin, estrogen and progesterone.¹ We believe (1) that an abnormal rise of chorionic gonadotropin after the twentieth week to a level of 200 rat units per hundred cubic centimeters of blood predicts in the diabetic premature delivery, stillbirth and neonatal deaths, (2) that these accidents are caused by a failure of production or of metabolism of estrogen and progesterone and (3) that they are prevented by continuous substitutional estrogen and progesterone therapy in replacement doses.

These conclusions are based on an analysis of sixty-one completed diabetic pregnancies treated and studied at the George F. Baker Clinic between January 1936 and June 12, 1940. The earlier hormonal analyses were made by Dr. George Van S. Smith and Mrs. Smith in their laboratory to complete their studies in the problem of preeclamptic toxemia of pregnancy, and the later ones have been done in the laboratory of the New England Deaconess Hospital, where we have attempted to establish them on a routine as well as on a research basis.

The sixty-one patients studied fall into three groups, twenty-five whose hormonal balance was normal, twelve whose hormonal balance was abnormal and uncorrected, and twenty-four whose balance was abnormal but who received substitutional estrogen and progesterone therapy.

The clinical course and outcome of the twenty-five normal hormonal diabetic pregnancies was uneventful. None developed preeclamptic toxemia, none had premature deliveries, and fetal survival was 92 per cent. One death was due to asphyxia pallida and one to hemorrhagic disease of the newborn. Contrast this experience with the course of the twelve patients whose values were abnormal and who received no therapy. Nine of the twelve developed preeclamptic toxemia, the remaining three had premature deliveries, and fetal survival was only 42 per cent. From this small group the pattern of behavior of pathologic diabetic pregnancies was clarified to us. Maternal and fetal behavior fell into two groups. After the abnormal rise of chorionic gonadotropin either the mother had a lightning-like toxemia, usually with hydramnios and delivery of a macerated stillborn child, or without toxemia was delivered prematurely of a mature-appearing atelectatic infant dying within a few hours of birth.

From the George F. Baker Clinic of the New England Deaconess Hospital, Elliott P. Joslin, medical director.

Read before the joint meeting of the Section on Obstetrics and Gynecology and the Section on Pediatrics at the Ninety-First Annual Session of the American Medical Association, New York, June 14, 1940.

1. White, Priscilla; Titus, R. S.; Joslin, E. P., and Hunt, Hazel: *Am. J. M. Sc.* 1938: 482 (Oct.) 1939.

Prevention of the accidents was our next problem. At the suggestion of the Smiths,² substitutional estrogen and progesterone therapy in replacement doses was started. Thirteen patients were given daily doses of from 150,000 to 450,000 international units of estradiol and from 10 to 40 mg. of benzoate proluton. Toxemia was controlled, premature deliveries did not occur, and fetal survival was 92 per cent. Though successful, this treatment would have been no more than a physiologic curiosity because of prohibitive cost but was supplied for these investigations through the courtesy of a manufacturer. Our next problem was the substitution of something inexpensive and preferably oral for estradiol benzoate and proluton. Through a grant from the National Research Council this study has been made possible, and eleven patients have been treated with oral stilbestrol in doses of 40 to 120 mg. daily and pregnolin 10 to 40 mg. daily, the stilbestrol being supplied through the courtesy of another manufacturer.

The clinical results are comparable: Toxemias were controlled, no markedly premature deliveries occurred and, barring one case of fatal erythroblastosis, the third erythroblastic infant of this mother, the fetal survival was excellent, 90 per cent. The one failure had perfectly controlled diabetes but imperfectly controlled hormonal balance, developed toxemia and delivered normally a typical gigantic macerated fetus.

Our present plan of treatment is oral therapy, but if the gonad stimulating factor called "prolan" is not falling to satisfactory levels after two weeks' adequate trial with stilbestrol in doses up to 120 mg. daily, stilbestrol given intramuscularly up to 50 mg. is substituted for the oral preparation. Among sixteen patients who have been or are being treated with massive doses of stilbestrol, no side reactions have occurred and no toxicity measured by bilirubin excretion tests has been observed.

Let us compare the fetal survival in our three groups: 92 per cent when the hormonal balance was normal, 42 per cent when the balance was abnormal and uncorrected and 87 per cent, including the case of erythroblastosis, when the abnormal balance was corrected.

The high level of late fetal mortality, namely 33 per cent, which was our yearly rate until 1938, is the one reported among diabetic clinics throughout the world. Obstetric hospitals have reported lower rates, we believe, because of the difference in patient clientele. Obstetric hospitals see many short duration cases with onset of diabetes in pregnancy, transitory hyperglycemia and glycosuria—patients whose clinical course and endocrine balance is different from that of chronically progressive diabetes. Diabetic clinics see more cases of diabetes of long duration with pregnancy incidental to the disease. Since our own practice is consultative, we refer back the borderline and short duration cases and deliberately select potentially abnormal cases. But the value of this presentation lies in this very fact—the obstetrician will see more patients of this type, for not only does one girl in 2,500 contract diabetes, but after many years' duration of the disease she will now live to the child-bearing age.

Delivery depends on clinical and hormonal behavior. Cesarean section is favored in the abnormal group, normal delivery in the normal group.

The treatment of diabetes is the simplest part of our problem. The diet must be adequate, carbohydrate liberal, from 150 to 250 Gm., protein 2 Gm. per

2. Smith, George Van S., and Smith, Olive Watkins: *Am. J. Obst. & Gynec.* 39: 405 (March) 1940.

kilogram of body weight, fat to complete the caloric prescription of 30 calories per kilogram. Medicinal minerals and vitamins are added. Insulin dosage, to avoid the pitfalls of low renal threshold, is controlled by blood rather than urinary sugars.

In a group of sixty-one patients we believe we have demonstrated that the accidents commonly seen in diabetic pregnancies are not due to imperfectly controlled diabetes but to an abnormal hormonal balance, a rise of chorionic gonadotropin, fall of estrogen and progesterone. These accidents are prevented by continuous substitutional estrogen and progesterone therapy in replacement doses. Finally, we believe that this treatment is no longer a physiologic curiosity but one well within the field of practical therapeutics.

81 Bay State Road.

THE NEONATAL PROBLEM IN INFANTS OF DIABETIC MOTHERS

WARREN R. SISSON, M.D.

BOSTON

Infants of mothers with diabetes mellitus show a high morbidity and mortality rate. My object in this paper is to present sixty-five consecutive infants of diabetic mothers studied during the past ten years. Such a group of infants was almost nonexistent two decades ago, before the insulin era. Women with diabetes either did not become pregnant or failed to give birth to a living child. Since the insulin era, the fecundity of the diabetic woman has greatly increased, and the juvenile diabetic patient has now reached the childbearing age. There is, therefore, an increasing number of pregnant women with diabetes mellitus and an increasing number of infants of diabetic mothers.

This group of infants has not been studied in large enough numbers to permit definite conclusions. There are sufficient data, however, to warrant certain general conceptions with regard to these infants. Miscarriages and stillbirths are most common in this group.¹ There has been a great variation in the mortality rate, and reports showing rates as high as 40 per cent have been recorded. A second conception is that these babies are unusually large and are frequently called "giant infants" at birth.² There is no evidence, however, to show that the skeletons of these infants are larger than normal or that these babies develop into larger types. A third conception from previous studies is that these infants are frequently born with hypertrophy of the islands of Langerhans. Recent work³ has shown that the majority of the infants studied have this condition, although it may also be found in normal infants. A further prevalent conception is that these infants frequently present symptoms due to hypoglycemia.⁴ For this reason it has been advocated that all infants of diabetic mothers be given parenteral dextrose immediately after birth. Recent observations,⁵ however, have not confirmed this idea.

Read before the joint meeting of the Section on Obstetrics and Gynecology and the Section on Pediatrics at the Ninety-First Annual Session of the American Medical Association, New York, June 14, 1940.

The material for the present study has been afforded by the clinic of Dr. Elliott P. Joslin of Boston. I myself have observed these sixty-five infants throughout the neonatal period. The care of the mothers has been uniform and has been modified only by newer concepts of diabetic treatment. One obstetrician has delivered all these babies.⁶ Analgesics prior to delivery were given to some of the mothers in this series. Most of the babies have been delivered by cesarean section under spinal anesthesia without preoperative medication. There have been no maternal fatalities.

The procedure adopted for the care of these babies has been as follows: The infant is immediately drained and all material obstructing the upper respiratory passages is removed by suction. If the infant is sluggish in breathing, no mechanical effort is made to resuscitate it. The baby is placed in an incubator with controlled conditions of heat, humidity and oxygen and left in this atmosphere for at least twenty-four hours. Nothing is given by mouth during this period. If the infant's condition is satisfactory, small doses of dextrose are started on the second day. From 1 to 2 drachms (4 to 8 cc.) of 5 per cent dextrose is given at first, and this amount is increased by from 1 to 2 drachms each feeding until 1 ounce (30 cc.) is given. All precautions are taken to avoid infection. Attempts have been made to have these infants nurse, but in general this has been unsuccessful. Microdeterminations of the blood sugar are made on the baby directly after birth and every four to eight hours during the first day. If symptoms do occur the oxygen atmosphere is continued and emphasis is placed on the importance of removal of material from the upper respiratory tract. It was a routine procedure during early observations to give parenteral dextrose directly after birth regardless of the blood sugar determinations. This procedure has not been carried out recently. A careful physical examination has been made on each infant during the first day of life. Tests for syphilis have not been made on these babies but tests on the mothers have given negative results in all cases.

This series of sixty-five infants of diabetic mothers has been divided for the purpose of study into three groups. The first group consists of thirty-seven infants, or 57 per cent of the total, who were normal at birth and whose course during the neonatal period was uneventful. There have been included in this group a few babies who were somewhat sluggish in breathing and who had minor degrees of cyanosis but who were not considered distinctly different from a great many so-called normal babies directly after delivery. Table 1 shows that 35 per cent of these infants were born of mothers who had had diabetes for from ten to twenty years and that 78 per cent of the infants were delivered by cesarean section. In this group 86 per cent were delivered between the eighth and the ninth month of gestation. The babies varied greatly in weight but the majority weighed between 6 and 10 pounds (2,720 and 4,535 Gm.). There were many mothers in this group who showed symptoms of preeclamptic toxemia.

The second group of this series consists of sixteen infants who survived but presented definite major symptoms, which generally occurred directly after delivery. These symptoms were not uniform. The infant would generally cry well at birth and be slightly sluggish in attaining normal color but at the end of two or three hours would develop a slight respiratory grunt. This

6. The mothers of the infants in this series were under the obstetric care of Dr. R. S. Titus and under the medical care of Dr. Priscilla White.

gradually became more accentuated, and the respirations often reached from 100 to 110 a minute. The reflexes usually became distinctly suppressed and crying could be elicited with difficulty. Jerky movements of the extremities were not infrequent and there invariably developed varying degrees of cyanosis. These symptoms usually persisted during the first twenty-four hours and rarely lasted more than two days. The baby's condition was generally improved by oxygen. Parenteral dextrose was given to a number of these infants without change in symptoms.

Physical examination of these infants directly after birth showed no demonstrable cardiac abnormality. The respiratory murmur over the lungs was frequently suppressed and was considered to indicate a marked degree of primary atelectasis. Some of the infants showed definite edema of the extremities and face.

In this group of sixteen infants, 31 per cent of the mothers had had diabetes for a period of from ten to twenty years (table 2). About a third of the mothers showed definite signs of preeclamptic toxemia with elevation of blood pressure, edema and albuminuria. Fifty per cent of these infants were delivered by cesarean section and all were born between the eighth and the ninth month of gestation. The weights of these babies were not unusual.

The following histories are examples of infants in this group who presented major symptoms:

REPORT OF CASES

CASE 29.—A female infant was delivered by cesarean section of a woman aged 24, who had had recognized diabetes for four years. The mother had been receiving approximately 14 units of regular insulin and 34 units of protamine zinc insulin late in her pregnancy. Her diabetes and pregnancy were uncomplicated. Her catamenia had been regular. This was her first pregnancy.

Cesarean section was done because the fetus was considered exceptionally large for the estimated eighth month of gestation. The baby at birth presented the appearance of a full term, mature infant. She weighed 8 pounds 10 ounces (3,912 Gm.). The dimensions were as follows: length 51 cm., head circumference 34 cm., thorax 33 cm. The delivery was performed under spinal anesthesia without preoperative medication. The placental attachment was beneath the uterine incision. The infant was not considered unusually cyanotic at birth and cried satisfactorily. There developed soon after birth a respiratory grunt, and considerable cyanosis of the extremities persisted. Thin yellowish fluid resembling amniotic sac contents was aspirated repeatedly from the trachea and recovered by postural drainage. There developed during the first few hours extreme degrees of general cyanosis with very shallow respiratory excursions. These attacks were apparently relieved by oxygen. The baby received 65 cc. of 5 per cent dextrose by hypodermoclysis six hours after birth. After twelve hours, because of persistent cyanosis, the baby was placed in a respiratory chamber in an atmosphere of helium and oxygen. The baby had no further marked cyanotic attacks but otherwise showed no improvement. At the end of the second day there were general hypotonicity, cyanosis of the extremities, no nursing reflex and a persistent respiratory grunt. Without any change in treatment, respirations gradually decreased from 120 a minute to normal, the

extremities became persistently pink and the baby cried vigorously. When about 60 hours old, the baby was taken out of the oxygen chamber and appeared essentially normal. No physical abnormalities were noted at this time and the infant's convalescence was uneventful. The baby lost 1 pound (450 Gm.) during the first four days. A solution of 5 per cent dextrose in teaspoon amounts was started after the infant was taken from the oxygen chamber.

The baby's blood sugar was 180 mg. per hundred cubic centimeters at birth, 170 mg. at 8½ hours, 160 mg. at 24 hours, 60 mg. at 32 hours and 60 mg. at 36 hours.

CASE 49.—A male infant was the first child of a mother, aged 25, who had had diabetes for fifteen years. Her disease was severe but well controlled. Her catamenia had been irregular but at the time of delivery physical examination suggested an eight months gestation. The pregnancy was uncomplicated except for a severe secondary anemia.

The baby was delivered by cesarean section under spinal anesthesia. Pentobarbital sodium 4½ grains (0.3 Gm.) was given preoperatively. The infant's birth weight was 6 pounds 6 ounces (2,892 Gm.). He reacted normally after birth. The cord blood sugar was 60 mg. per hundred cubic centimeters. Four hours after birth he became very cyanotic. Eight hours later the condition became worse, respirations were very shallow and convulsive movements of the extremities developed. The baby was considered moribund. At this time the blood sugar was 9 mg. per hundred cubic centimeters. Thirty cc. of 10 per cent dextrose solution was given by gavage and clinically there was great improvement in the patient's condition. The blood sugar rose to 30 mg. on the second day and to 80 mg. on the third day. He lost 10 ounces (283 Gm.) but showed no further symptoms. His reactions suggested an immature infant. Physical examination was negative and the future course was normal.

The mother was given insulin preoperatively and showed symptoms of insulin shock after delivery. Her blood sugar at that time was 50 mg. per hundred cubic centimeters.

CASE 1.—A male infant was born of a mother, aged 27, who had had diabetes for twenty years. She was a very small person, weighing about 100 pounds (45 Kg.), but members of her family were large and her husband was of average size. The mother's catamenia had been regular and this was her first pregnancy. She had many complications of diabetes and evidence of toxemia, with elevation of blood pressure and edema of the extremities. The latter disappeared with rest in bed and treatment with stilbestrol and pregnolinine. The baby was delivered under spinal anesthesia without preoperative medi-

cation by cesarean section about three weeks before term. The mother's dosage of insulin at this time was 22 units of regular and 32 units of protamine zinc insulin daily. There was definite hydramnios.

The infant weighed 9 pounds 14 ounces (4,480 Gm.) and cried lustily at birth. He passed meconium before complete extraction from the uterus. Considerable fluid was drained and greenish material aspirated by catheter. He remained moderately cyanotic for six hours. He had definite apnea and his respirations were irregular, shallow and rapid, increasing to 120 a minute. He was kept in an incubator in an oxygen atmosphere of from 40 to 60 per cent. He had no convulsions. At about 36 hours he was normal and his course was uneventful. He lost 11 ounces (312 Gm.). Physical examination showed no abnormalities. His head was 35 cm. in circumference, thorax 35.6 cm. and length 52 cm.

An x-ray film was taken after twenty-four hours which showed shadows typical of multiple atelectatic areas, suggestive

of inhalation of amniotic sac contents. The blood sugar at 2 hours was 100 mg. per hundred cubic centimeters, at 5 hours 120 mg., at 9 hours 140 mg., at 14 hours 140 mg. and at 23 hours 120 mg. Dextrose solution was started by mouth at 25 hours of age.

The third group of this series of infants of diabetic mothers consists of twelve infants who died during the first three days of life (table 3). The symptoms that these infants presented showed great variation, and there was no common cause for death. The first three infants of this group died of recognized conditions. In cases 32 and 38 the fetuses were nonviable, delivered spontaneously in the fourth or fifth month of gestation. The remaining seven infants of this group were delivered from one to two months prematurely. The weights of these infants, with two exceptions, were from 6 to 8 pounds (2,720 to 3,630 Gm.). These seven infants presented symptoms of anoxia and died within one to fifteen hours after birth. The symptoms of this group of infants were often similar to those observed in the second group except that they were associated with greater degrees of cyanosis and asphyxia. Dyspnea did not seem such a prominent symptom as in the previous group.

occurred. Apnea developed and this was relieved by artificial respiration and suction. Considerable fluid, suggesting amniotic sac contents, was recovered from the pharynx. She was given 50 cc. of 5 per cent dextrose by hypodermoclysis twelve hours after birth. The baby had a severe cyanotic attack three hours later and efforts to establish respiration were unsuccessful.

The cord blood sugar was 117 mg. per hundred cubic centimeters. At 4 hours the blood sugar was 90 mg. and at 12 hours 60 mg. per hundred cubic centimeters.

The clinical diagnosis was prematurity and asphyxia neonatorum. An autopsy was performed which showed primary atelectasis of the lungs, marked hemopoiesis of the liver and some hemorrhage of both adrenals. The pancreas appeared normal. No definite cause of death was determined.

The second baby, a boy, was regarded as normal at birth and weighed 6 pounds 1 ounce (2,750 Gm.). He presented no problems of resuscitation. Physical examination shortly after birth showed that he was a well developed infant with dimensions of the head and thorax somewhat below the average. There was no demonstrable pathologic condition of the heart and abdominal organs. The respiratory note was distinctly suppressed, especially over the upper lobes of the lungs and the left lower lobe. No rales were heard. The respirations were shallow and there was some thoracic retraction. General cyanosis was noted about two hours after birth, which increased but was modified somewhat by high concentrations of oxygen. Mild convulsive movements of the arms and muscles of the

TABLE 3.—Twelve Deaths of Infants of Diabetic Mothers

Case	Mothers				Weight		Duration of Life	Infants	
	Duration of Diabetes	Medication	Delivery	Gestation	Pounds	Ounces		Clinical Diagnosis	Anatomic Diagnosis
4	8 yrs.	Yes	Normal	9 mos.	6	3	40 hrs.	Erythroblastosis	Erythroblastosis
5	3 yrs.	Yes	Normal	9 mos.	7	3	72 hrs.	Hemorrhage of adrenals	No autopsy
53	1 yr.	No	Breech	9 mos.	6	12	20 hrs.	Cerebral hemorrhage	Tentorial tear, cerebral hemorrhage
32	4 yrs.	No	Normal	5 mos.	3	12	45 min.	Prematurity, asphyxia	Cause of death?
38	4 yrs.	No	Normal	5 mos.	3	..	1 hr.	Prematurity, asphyxia	No autopsy
39	3 yrs.	Yes	Breech	7 mos.	4	4	8 hrs.	Prematurity, asphyxia	Prematurity
36	14 yrs.	Yes	Cesarean	7 mos.	6	12	1½ hrs.	Prematurity, asphyxia	Primary atelectasis, partial
40	4 yrs.	Yes	Cesarean	8 mos.	8	1	2½ hrs.	Asphyxia	Prematurity, cause of death?
42	8½ yrs.	Yes	Cesarean	7½ mos.	6	4	10 hrs.	Prematurity, asphyxia	Aspiration of amniotic fluid
41	1 yr.	No	Low forceps	7 mos.	7	..	14 hrs.	Atelectasis, intracranial hemorrhage?, asphyxia	Primary atelectasis
37	11 yrs.	Yes	Breech	7 mos.	4	8	15 hrs.	Prematurity, asphyxia	Primary atelectasis
17	12 yrs.	No	Cesarean	8 mos.	6	1	10½ hrs.	Asphyxia	Cause of death?

Autopsies were performed in ten of the fatal cases and the exact cause of death was determined in two. Primary atelectasis was frequently noted. Evidence of aspiration of amniotic sac contents, hemorrhage of various organs and areas of hemopoiesis was common. Marked hyperplasia of the islands of Langerhans was noted in only one case.

The following histories are examples of infants who died:

CASES 37 and 17.—These two infants were born of the same mother in successive years and were the only pregnancies. The mother was 23 years old at the time of the first pregnancy and had had diabetes for eleven years. She was receiving 28 units of protamine zinc and 16 units of regular insulin during the second pregnancy. Her catamenia had been regular. Her first pregnancy was not associated with the usual signs of toxemia but before the birth of the second baby she had slight edema. The first baby was delivered by breech extraction under nitrous oxide and oxygen anesthesia two months before term. The mother received pentobarbital sodium 4½ grains (0.3 Gm.) and scopolamine ½150 grain (0.0004 Gm.) about four hours before delivery. The second baby was delivered under spinal anesthesia without preoperative medication shortly after the eighth month of gestation.

The first baby, a girl, weighed 4 pounds 8 ounces (2,040 Gm.) and was cyanotic and atonic at birth, with suppression of all reflexes. The general appearance was that of a small, immature infant. She was placed in an incubator with a mixture of helium and 45 per cent oxygen, which relieved the cyanosis temporarily. During the next five hours severe attacks of cyanosis

face developed. About four hours after birth he was given 75 cc. of 5 per cent dextrose by hypodermoclysis and 25 cc. two hours later, without a change in his condition. The cyanosis became more extreme, periods of apnea developed with increased suppression of all reflexes and the infant died about ten and one-half hours after birth.

The blood sugar determinations were 170 mg. per hundred cubic centimeters at birth, 40 mg. at 3 hours and 140 mg. at 9 hours.

The clinical diagnosis was asphyxia neonatorum. An autopsy revealed no evidence of cerebral abnormality. "The lungs were unexpanded and rubbery, noncrepitant and red throughout. Microscopically, only few alveoli were expanded. The pancreas showed moderate hypertrophy and hyperplasia of the islands of Langerhans with increase of the size of the islands and cells. The immediate cause of death was undetermined." The blood sugar level of the heart was 22 mg. per hundred cubic centimeters and of the liver 27 mg.

COMMENTS

Blood sugar determinations by the Folin-Malmros micromethod, as described by McKittrick,⁷ were made on a large number of infants in this series. The purpose of these studies was to determine, if possible, any relationship between existing symptoms of infants of diabetic mothers and the blood sugar levels. Although determinations were made during the first three days in a large number of cases, only the results of the determinations during the first twelve hours are noted, as

7. McKittrick, J. B.: Serial Blood Sugar Determinations in Normal Newborn Infants, *J. Pediat.* 16: 151 (Feb.) 1940.

invariably symptoms noted in this series of infants occurred during this period (table 4 and chart 1). It will be seen that the maximum blood sugar levels during the first twelve hours were unusually high, namely from 170 to 260 mg. per hundred cubic centimeters, and that

Chart 1.—Curves of maximum, average and minimum blood sugar values, based on determinations made on fifty infants born of diabetic mothers.

the average blood sugar levels during this period were much above the level usually described as normal for an infant of this age. The minimum levels were somewhat lower than the expected but, with one exception, were not unusual, especially if one compares the values given for normal immature infants during the first forty-eight hours of life, as noted by Miller and Ross.⁵ The finding of 9 mg. per hundred cubic centimeters was noted in one infant (case 49), whose mother had had a large dose of insulin shortly before delivery and developed an insulin reaction after the birth of the baby. This infant's condition was greatly improved after the administration of dextrose. It is obvious from these studies that the infants in this series presenting major symptoms during the first twelve hours may have normal

or more, and seven babies who weighed 9 pounds (4,080 Gm.) or more. Studies of these babies through the neonatal period and infancy have offered no evidence that skeletally these infants were larger than normal. There have been many instances in which infants have been delivered from one to two months prematurely and have weighed 8 pounds or more.

This study of sixty-five consecutive infants of mothers with diabetes mellitus emphasizes again the high morbidity and mortality rates in the neonatal period. In this series 43 per cent of the infants, as shown in table 5, showed clinical symptoms, and 18 per cent of the sixty-

TABLE 5.—Outcome of Sixty-Five Infants Born of Diabetic Mothers

Group	No. of Cases	Per Cent	Result

five died. In two of the fatalities the fetuses were undoubtedly nonviable, a third had erythroblastosis, a fourth had cerebral hemorrhage with a tentorial tear and a fifth probably had hemorrhagic disease of the newborn. If these five fatalities are excluded, a corrected mortality rate would be 11 per cent. The symptoms that these infants presented cannot be regarded as specific of the infant of the diabetic mother, but there seems to be a rather typical symptom complex. It usually occurs in the first twelve hours of life and is associated with frequent and labored respirations. A moderate degree of cyanosis also is seen, but this is not extreme except in the terminal stages. Physical examination in general shows evidences of unexpanded lungs and occasional edema of the subcutaneous tissue. All reflexes are suppressed, but muscular contractions of the face and extremities are not uncommon. The cause of these symptoms cannot be explained by the use of analgesics and anesthetics, since most of the infants were delivered under spinal anesthesia without preoperative medication. The condition suggests an

TABLE 4.—Blood Sugar Determinations—Males and Females

blood sugar levels, as seen in chart 2. Furthermore, it was a common experience that parenteral administration of dextrose failed to relieve the symptoms, as illustrated in chart 2 (case 17).

It has been impossible to add accurate data in this series with regard to the possible effect of maternal diabetes on the weight of the infant. The problem is complicated by the fact that many women with diabetes have an irregular catamenia and also by the fact that 63 per cent of the infants studied were delivered by cesarean section before term. It is the distinct impression from observations at hand that the infants in this series weighed more than the average and that this is due to an excess of adipose tissue. There were fourteen babies in this series who weighed 8 pounds (3,630 Gm.)

Chart 2.—Curves of blood sugar values of three infants born of diabetic mothers.

intra-uterine cause with involvement of the respiratory center. In many instances a precipitating cause has seemed to be the insufflation of amniotic sac contents.

The symptoms appear to have little relationship to the severity or duration of the mother's diabetes, as seen in table 6. Delivery by cesarean section did not appear to have an unfavorable effect on the infant, as

78 per cent showing a normal course were delivered by this method. Symptoms occurred almost twice as frequently if the infant was delivered in the eighth month of gestation, and 58 per cent of the fatal cases occurred when the infant was delivered in the seventh month. Although this study may clearly suggest the unfavorable influence of interrupting gestation before the eighth month, it should be remembered that the incidence of miscarriages and macerated fetuses among infants of diabetic mothers is not uncommon, and therefore prolonging gestation may be a greater hazard than inducing premature birth.

The study on the blood sugar levels of these infants has been disappointing as far as showing any relationship between the presenting symptoms and hypoglycemia. Experience showed early in the study the importance of maintaining a high maternal blood sugar level before delivery of the infant. It is probable that this fact modified our procedure with regard to the routine administration of parenteral dextrose to the infant of the diabetic mother directly after delivery.

TABLE 6.—*Relation of Diabetes, Type of Delivery and Period of Gestation to Viability of Fetus*

Fatalities	12	75%	25%	33%	67%	58%	17%	25%	33%

CONCLUSIONS

1. In a consecutive series of sixty-five infants born of diabetic mothers, 57 per cent were normal and 43 per cent presented symptoms in the neonatal period. The mortality rate was 18 per cent.

2. The symptoms presented by these infants varied greatly and were caused by many conditions. Cerebral anoxia with involvement of the respiratory center appears to be the cause of many of the symptoms presented by these infants.

3. All infants of diabetic mothers should be adequately drained and placed in an atmosphere of from 40 to 50 per cent oxygen immediately after birth.

4. Infants of diabetic mothers in this series showed high blood sugar levels. Hypoglycemia is a rare complication but may occur if insulin is given the mother shortly before delivery. The routine administration of parenteral dextrose immediately after birth is not indicated.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. WHITE AND HUNT AND DR. SISSON

DR. J. A. LAMPHIER, Brooklyn: At the Long Island College Hospital we have observed with considerable interest Dr. White's work regarding the relationship of toxemia in diabetic pregnancies. However, the tremendous dosages and the cost of the drugs have made it beyond our employment for practical application at our clinic. The substitution of stilbestrol for estrogen solves this problem and has answered the question I had in mind. I did not get the name of the substitution therapy for progesterone. I should like to know what drug Dr. White substitutes for progesterone, also the average dose and the average cost of this preparation.

DR. PRISCILLA WHITE, Boston: We have been substituting pregnenolone for progesterone, and we are using less than 50 cents' worth a day. Usually we use only 10 mg. In a few cases we have had to use more than that.

TESTS OF PANCREATIC FUNCTION

MANDRED W. COMFORT, M.D.

ROCHESTER, MINN.

The pancreas is composed of acini lined with columnar cells; between the acini are small groups of cells termed interalveolar cell islets (islands of Langerhans). There are two main types of cells in the islands of Langerhans, distinguished as alpha and beta cells according to special staining reactions of the granules which they contain. The functions of the acinar cells and of the beta cells of the islands of Langerhans are comparatively well defined and progress is being made in the study of the functions of the alpha cells. Tests whereby the functions of each type of cell may be studied will be reviewed, and the clinical use of such tests will be described.

TESTS FOR DISTURBANCES OF EXTERNAL SECRETION OF ACINAR CELLS

The external secretion of the acinar cells is carried by the pancreatic duct to the duodenum. This secretion is under the control of both nervous (vagal) and chemical (secretin) mechanisms. Stimulation of the vagus mechanism produces a juice rich in enzymes, while stimulation of the secretin mechanism produces a juice rich in carbonate. The external secretion of the pancreas thus serves two distinct functions: it acts as a diluting and neutralizing fluid and it provides enzymes important in digestion.

Analysis of Duodenal Content.—Among the earlier tests may be mentioned those in which the gastric content was examined after the administration of test breakfasts and those in which the urine was examined for substances liberated by digestion of capsules swallowed by the patient. These methods have only a historical interest now. Worth while clinical study of secretion of enzymes by the pancreas may be said to have begun with the description of the duodenal tube by Einhorn in 1908. Then, following the establishment of physicochemical conditions governing the activity of enzymes by Sorensen in 1909, adequate methods of chemical analysis were devised, among others by McClure and his associates¹ and by Willstätter and his associates. Many excellent data have been obtained by use of the single barrel tube similar to that described by Einhorn to remove for analysis the fasting content of the duodenum or the content of the duodenum after stimulation with various inorganic substances as well as food. However, a more accurate technic of removing the duodenal content as well as more powerful stimulants now available are requiring restudy of analysis of the duodenal content as a test of external pancreatic function.

Ågren and Lagerlöf² combined previously described methods³ and used a two barrel tube; one barrel entered the stomach and the other entered the duodenum, to

From the Division of Medicine, the Mayo Clinic. Owing to lack of space this article is abbreviated in THE JOURNAL. The complete article appears in the author's reprints.

3. Lim, R. K. S.; Matheson, A. R., and Schlapp, W.: An Improved Method for Investigating the Secretory Function of the Stomach and Duodenum in the Human Subject, Quart. J. Exper. Physiol. 13:353-345, 1922-1923.

remove continuously and separately the gastric and duodenal contents under negative pressure. This technic has eliminated two variables acting on the external pancreatic secretion: first, the intermittent and uncontrolled stimulation of the secretin mechanisms by the entrance of acid gastric content into the duodenum and, second, the diluting effect of the gastric content. It has permitted the quantitative removal of the duodenal content, fractionation of the content as desired and, finally, calculation of the total enzyme activity per unit of time as well as the concentration for each sample. These accomplishments were impossible when the single tube was used. Moreover, the administration parenterally of potent stimulants has insured responses approaching a maximum. Two types of stimulants have been used, one purified secretin and the other those drugs which stimulate the vagus mechanism; each gives characteristic types of secretion and makes possible the selective study of the two functions of external secretion of the pancreas.

Technic of Removal of Duodenal Content with the Double Barrel Gastroduodenal Tube: After a fast of twelve hours a two barrel gastroduodenal tube is introduced into the duodenum. The structure of the tube is diagrammatically shown in figure 1. It is to be noticed that a length of tubing without perforations lies between the perforations in the stomach and those in the duodenum. When the tube is in the correct position that particular portion of the tube not perforated occupies the pyloric portion of the stomach and duodenum. That the tube occupies the correct position is determined by roentgenologic examination of the abdomen. A negative pressure of from 25 to 40 mm. of mercury has been found to be sufficient to prevent to a great extent overflow of gastric juice into the duodenum and for the collection of the duodenal content.

A half reclining position for the patient has been found satisfactory. At the clinic it has been our practice to fractionate the duodenal content into four periods of ten minutes each before stimulation and into four periods of ten minutes each and two periods of twenty minutes each after stimulation.

Secretin as a Stimulant: Physiologists, no doubt, have looked forward to the development of a test of pancreatic function using secretin as a stimulant, since its discovery by Bayliss and Starling in 1902. Although secretin was administered intravenously to a few patients as early as 1926,⁴ it was not until 1934⁵ and 1936⁶ that extensive studies of external pancreatic function were carried out. In most of these studies the single barrel duodenal tube was used to remove the duodenal content. Ågren and Lagerlöf, however, employed the double barrel duodenal tube and reported more results in 1936 that seemed to picture more accurately the type of secretory response to secretin. Their results have been confirmed by Diamond and his associates⁷ and by Osterberg and me.⁸

The effect of secretin administered intravenously is noticeable within a short period of time, usually in a minute. Normal biliary color of the duodenal content rapidly becomes less marked and in many instances a clear, almost colorless secretion is obtained, provided the gallbladder is functioning. The yellowish color of the duodenal content reappears after a short time. In normal persons following stimulation with secretin the volume of duodenal content increased markedly and rapidly, usually reaching its peak within the first ten minute period. The hydrogen ion concentration usually increased one unit and reached a value of 8 or more. The carbonate content increased, roughly paralleling the behavior of the volume. The concentration of enzymes in the juice declined, reaching its low point in the second ten minute period. The total value for each enzyme per unit of time was increased but the increase was almost entirely limited to the first ten minute period,

Fig. 1.—Double barrel gastroduodenal tube; one barrel ends in the stomach, the other in the duodenum.

particularly in the case of amylase and trypsin. The increase in total values appears to be due to a washing out of preformed enzymes and not due to any effect of secretin on the formation of enzymes.

The volume, alkalinity, concentration and total excretion of enzymes may be used to detect pancreatic dysfunction, as illustrated in the following case of chronic pancreatitis:

A youth aged 18 years, who registered at the clinic Dec. 12, 1938, had noted a beginning of chronic epigastric soreness, fulness after eating and two or three soft or watery stools daily in June 1937. In December 1937 a severe attack of midepigastric pain extending to the dorsal region required the administration of morphine for relief. Five additional severe attacks had occurred since that time, the last one in September 1938, but three or four mild attacks had occurred weekly. On physical examination slight tenderness in the epigastrium was the only abnormality found. Urinalysis did not disclose glycosuria and the concentration of sugar in the blood was within normal limits but the test for tolerance for dextrose showed a diabetic curve. Hemoglobinemia was present. Leukocytes numbered 15,600 per cubic millimeter, and 81 per cent were neutrophils. The lipolytic activity in terms of twentieth-normal

sodium hydroxide per cubic centimeter of serum was 2.5 cc. and the amylolytic activity in terms of units was 530. A diagnosis of chronic pancreatitis was made and confirmed at exploration in May 1939.

A test of function of external pancreatic secretion using purified secretin intravenously as a stimulant was performed. Figures 2, 3 and 4, in which the values

Fig. 2.—Large volume of duodenal content recovered per unit of time from a patient with chronic pancreatitis, after stimulation with secretin and with acetyl beta-methylcholine chloride, contrasted with the volumes obtained from normal persons.

obtained in this case are contrasted with the extremes as well as the means obtained in normal persons, demonstrate a hypersecretion of the pancreatic juice (fig. 2), a normal increase in values for hydrogen ion concentration but a marked hyposecretion of amylase. The values for concentration of amylase did not exhibit the typical decrease in concentration consistently seen in the second ten minute period (fig. 3) nor did the total values for amylase exhibit the usual marked increase during the first ten minute period (fig. 4). There was, in contrast, a hypersecretion of trypsin and lipase. Ågren, Lagerlöf and Berglund⁹ have called attention to the frequency with which pancreatic injury causes a marked reduction in secretion of amylase without interfering with the secretion of fluid, bicarbonate or trypsin and suggested that this represents the mildest form of injury in pancreatitis. Chiray and Bolgert⁶ recognized both a dissociated trypsin and a lipolytic insufficiency. In those cases in which obstruction of the pancreatic duct or destruction of pancreatic tissue occurs, as in cases of carcinoma or fibrosis of the pancreas, there is a decrease in the volume of secretion and the secretion of all the enzymes may be affected in proportion to the destruction of tissue and the degree of obstruction of the duct. Secretin used as a stimulant of pancreatic secretion should prevent the occurrence of false low total values and should disclose the more marked disturbances of secretion of fluid, alkali and the three enzymes. However, inspection of figures 3, 4 and 5 shows that mild reduction of values will not become apparent because of the variations in normal values among normal persons. While the number of published reports of tests in proved pathologic states of the pancreas is relatively small, these as well as my own experiences with the test leave little doubt

in my own mind concerning the value of secretin for clinical study of the secretion of fluid, carbonate and enzymes by the acinar cells.

Drugs Which Stimulate the Vagus Mechanism: Pilocarpine, acetylcholine, acetyl beta-methylcholine chloride, physostigmine and prostigmine have all been used to stimulate pancreatic secretion. These drugs produce a secretion rich in enzymes and in this respect their action is similar to that of stimulation of the vagus nerve in animals. Osterberg and I⁸ have used the two barrel gastroduodenal tube, continuous suction and acetyl beta-methylcholine chloride administered subcutaneously in doses of 15 mg. to obtain a picture of the type of secretory response obtained. Following stimulation with mecholyl chloride (acetyl beta-methylcholine chloride) a small increase in volume occurs; there is no significant change in the hydrogen ion concentration but there is an increase in the concentration of enzymes which is prolonged in duration. The total values for the several enzymes per unit of time increase for thirty minutes or longer and appear to be due to an actual increase in the secretory output of enzymes. Contrasting effects of secretin and mecholyl chloride are well illustrated in figures 2, 3 and 4, which show the extremes as well as the means for the several values obtained from normal persons.

In the case of pancreatitis already presented in abstract form, external pancreatic secretion was also studied after stimulation with mecholyl chloride. Analysis of duodenal content after administration of this drug demonstrated a hypersecretion of fluid (fig. 2), a marked insufficiency of secretion of amylase (figs. 3 and 4) but a hypersecretion of trypsin and lipase, as was the case after secretin. The same dissociation of enzymatic insufficiency that occurred after stimulation with secretin is likewise seen when using mecholyl chloride as a stimulant. A generalized reduction below the normal range of values for volume of fluid and of enzymes occurs after stimulation with mecholyl chloride in cases

Fig. 3.—Low concentration of amylase in the duodenal content recovered per unit of time from a patient with chronic pancreatitis, after stimulation with secretin and with acetyl beta-methylcholine chloride, contrasted with the concentrations obtained in the duodenal contents recovered from normal persons.

of obstruction of the pancreatic duct and in cases of destruction of the acinar cells. Diminution of concentration as well as in total output of enzymes may give some inkling of pancreatic insufficiency. Drugs of this group and particularly mecholyl chloride should be valuable in the study of secretion of enzymes but are of

no value in studying secretions of carbonates. Foods are distinctly less powerful stimulants of pancreatic secretion than are either secretin or mecholyl chloride.

Analysis of Stools for Enzymes.—Amylase and trypsin are normally present in the feces. Lipase usually cannot be detected. Wolfer and Christian¹⁰ have pointed out that the amylase in the stools varies from day to day depending on the intake of food, and if the test is to be used clinically it can be effective only if the patients are placed on a uniform quantitative and qualitative diet. Even when using twenty-four hour specimens there is no constant relation between the amounts of amylase either of patients on the same diet or of the same persons from day to day, although the weekly totals approximate one another closely. Decreased values for fecal amylase occur in cases of obstruction to the duct and in extensive disease of the pancreas.^{10a} Wolfer and Christian do not feel that mild involvement of the pancreas can be confirmed by determinations of fecal amylase.

Examination of the stools for enzymes has not proved to be a popular method for study of external pancreatic function for obvious reasons.

Analysis of Stools for Undigested and Unabsorbed Food.—Many observations have shown that all food-stuffs are lost in excess in the presence of pancreatic disease and have led to the gross and microscopic examination of the stools and chemical examination of the stools for undigested foods as aids in the diagnosis of chronic pancreatic disease.

Gross Appearance of Feces: The excessive loss of fat in the stools lends the characteristic appearance to the stools of pancreatic disease. Fat may be lost in the form of neutral fat, fatty acids or soap. A fatty stool may be glistening white or gray. Fat may appear as liquid fat or as masses of fat resembling butter. Fatty crystals may give the feces the appearance of aluminum paint. According to Thaysen,¹¹ the only form of steatorrhea which is characteristic of pancreatic disease is that in which liquid fat or masses of fat appear in the stools.

Microscopic Examination of Feces: A description of the microscopic method of examination may be found in any standard textbook on laboratory diagnosis. An excess of all food remnants may appear in the feces from excessive ingestion as well as from deficient digestion and absorption. For this reason it is preferable to carry out microscopic examinations of the stools only when patients are receiving a standard test diet, such as that of Schmidt. It is doubtful that finding microscopically any foodstuff in excessive amounts is diagnostic of pancreatic disease, as such tests of necessity must be qualitative. The finding of striated muscle fibers in excess possibly has more significance than the finding of starch granules and fat in excess, but it is best to let such observations serve as an indication for more specific tests of pancreatic function and not depend on them to diagnose the cause of the loss of food.

Chemical Analysis of Feces: In carrying out chemical analysis of the stools, the patient is placed on a

standard diet such as that of Schmidt. In persons with normal digestive apparatus, digestion and absorption is fairly complete; the values for nitrogen, carbohydrate and fat in the stools seldom exceed 10 per cent of the values for nitrogen, carbohydrate and fat in the ingested food but vary somewhat with the digestibility of the food eaten. All foods are lost in excess when extensive destruction of the acinar cells of the pancreas has occurred.

Thaysen's review of the percentages of various foods lost in the feces in his own cases and in those recorded in the literature leads to the conclusion that such determinations would possibly be of limited value in distinguishing between pancreatic disease and diseases that affect intestinal absorption.

TESTS FOR DISTURBANCES OF THE "INTERNAL" SECRETION OF ACINAR CELLS

The enzymes lipase and amylase normally are active to a slight degree in the blood stream. Tryptic activity in the blood stream is said to be absent in normal per-

Fig. 4.—Total amount of amylase in the duodenal content recovered per unit of time from a patient with chronic pancreatitis, after stimulation with secretin and with acetyl beta-methylcholine chloride, contrasted with the total amount obtained in the duodenal contents recovered from normal persons.

sons but this enzyme has not been studied widely. Satisfactory evidence that the enzymes lipase and amylase arise partly in the pancreas may be cited; this may mean that they are in part at least an internal secretion of the pancreas, but it is not known whether they enter the blood stream directly from the acinar cells or indirectly from the gastrointestinal tract. Nevertheless, classification of values for enzymes in serum and urine as tests of internal secretion of the acinar cells is open to criticism; however, it is convenient to do so and serves to emphasize that the increased content of enzyme in the serum and urine in the presence of benign and malignant lesions of the pancreas originates in the acinar cells of the pancreas.

The factors which maintain the normal concentration of enzymes in the serum in health are not well understood. It is believed that the liver plays a role¹⁴ and that the anterior lobe of the pituitary gland,¹⁵ the thy-

roid gland¹⁶ and the adrenal gland¹⁷ exert some influence. The elevated values for enzymes which occur experimentally and clinically in inflammatory disease of the pancreas and in experimental and clinical obstruction of the pancreatic duct presumably have occurred as a result of rupture of small pancreatic canaliculi permitting entrance of pancreatic juice into the blood stream, perhaps through the lymphatic vessels, but it is also possible that irritative lesions of the acinar cells provoke a hypersecretion with increased values while destruction of the acinar cells prevents the appearance of increased values.

Determination of Values for Lipase and Amylase in the Serum.—Measurement of lipolytic and amylolytic activity can be accomplished by either physical or chemical methods. Among the methods available, those recently described by Cherry and Crandall¹⁸ for the determination of lipolytic activity and by Somogyi¹⁹ for the determination of amylolytic activity in the serum have been proved satisfactory. The simple titration method of Cherry and Crandall uses olive oil as the

Fig. 5.—The behavior of concentrations of lipase and of amylase in the serum in cases of acute pancreatitis; the concentration of amylase usually returns to normal levels earlier than that of lipase.

substrate and it expresses lipolytic activity in terms of cubic centimeters of twentieth-normal sodium hydroxide liberated by 1 cc. of serum. The method of Somogyi employs iodine to measure the rate of disappearance of starch, and the values are defined in terms of units. Osterberg and I²⁰ have found it advisable to use 1.5 cc. of twentieth-normal sodium hydroxide and 320 units as the upper limits, respectively, for lipolytic and amylolytic activity in the serum. These values are considerably higher than those originally proposed for the upper limit of values for normal persons.

Elevated values in the serum occur within a few hours after the onset of acute inflammation of the pancreas,²¹ reaching a maximum within forty-eight to seventy-two hours (fig. 5). Elevated values for lipase usually return to normal within ten to fourteen days but elevations may persist over a long period of time; thus, elevated values for lipase have been obtained in every determination made over a period of months in the case of chronic pancreatitis reported herein. On the other hand, elevated values for amylase in the serum usually return to normal within a week,²² often earlier, although elevated values following experimentally produced pancreatitis have been found to persist as long as from eight to fifteen days.²³

Elevated values occur with great frequency in association with pancreatitis without associated disease of the biliary tract and in cases of pancreatitis secondary to disease of the biliary tract, provided the determinations are carried out within a few days after an acute attack of upper abdominal pain or during the acute stage of obstruction of the pancreatic duct. Osterberg and I²⁰ have laid down rigid criteria to be used in the interpretation of results in a recent analysis of our data. We expected elevated values in every case in which pancreatitis was described by the surgeon as subacute or acute, with or without fat necrosis, or as extensive (graded 3 to 4 on the basis of 4), provided determinations were carried out within seven to ten days of an acute attack of upper abdominal pain or, in other words, within the times during which elevated values could reasonably be expected. In these cases in which the pancreatitis was assumed to be active and acute, elevated values for lipase were obtained in 97 per cent of cases; a single low normal value occurred in a case of hemorrhagic pancreatitis in which a failure of values for lipase to increase was attributed to rapid and complete disintegration of the pancreas with destruction of the lipase producing tissue. More important, the condition of the pancreas was accurately indicated in 97 per cent of cases of disease of the biliary tract in which the condition of the pancreas was described by the surgeon.

The percentage accuracy of the determinations of amylase in the serum in the diagnosis of active pancreatitis was not quite so great as that of lipase, but this is probably due to the more rapid return of values for amylase to normal following an acute attack. Increased values for amylase and lipase in the serum have likewise occurred in cases of pancreatitis secondary to perforating benign and malignant lesions of the stomach and duodenum.²⁴ Increased values for lipase serum have been reported in 40.5 per cent of cases of carcinoma of the head of the pancreas, whereas those for amylase occur in only 8 to 22 per cent.²⁵ Elevated values have occurred in about 10 per cent of cases of hepatic disease, whereas elevated values for amylase

have not been reported in disease of the liver.²⁶ No good reason has so far been advanced for believing that these or other elevations are due to causes other than involvement of the pancreas by a disease. In short, elevated values occur in association with benign and malignant obstruction of the pancreatic duct and with inflammation of the pancreas situated primarily in the organ or involving it secondarily from diseases in the neighboring organs.

Determination of Values for Amylase in the Urine.—It is accepted that amylase in the urine is derived from the blood, that a rise in urinary diastase occurs within one to two hours after an acute attack of pancreatitis begins and shortly after the rise in blood amylase, and that the increase lasts from thirty-six to forty-eight hours and then falls suddenly and is usually normal in from three to four days. Elevations occur also during exacerbations of chronic pancreatitis. Renal damage may interfere with the excretion of amylase. Elevated values occur in cases of acute pancreatitis unassociated with disease of the biliary tract, in cases of acute pancreatitis secondary to disease of the biliary tract and duodenal ulcer penetrating into the pancreas, but rarely in cases of carcinoma of the pancreas. Wohlgemuth's original method or some modification of his method has usually been used for the determination of amylolytic values in the urine. Somogyi's method has gained favor recently.

Determinations of amylase in the urine as a test of disturbance of internal secretion of the acinar cells has been widely used for many years²⁷ and many conflicting opinions about its accuracy in the diagnosis of pancreatic disease have been expressed. As one reads the reports of the various investigators, the thought arises that the discouraging reports of early investigators were possibly due to ignorance of the relatively short duration of elevations of values following an acute attack and the lack of knowledge of the milder degrees of pancreatitis, and that elevated values previously thought due to cholecystitis and common duct stone were probably for the most part due to pancreatitis of a mild degree associated with the disease of the biliary tract, a type of pancreatic inflammation not widely recognized at the time when the studies were made.

It may be accepted, for the present, that elevated values for lipase and amylase in the serum and for amylase in the urine usually point to disease of the pancreas; that the pancreatic disturbance may be primary in the pancreas or secondary to disease of the biliary tract, to benign or malignant disease of the stomach, to duodenal ulcer or even to stasis in the pancreas; that determinations of the concentrations of enzymes do not allow for a diagnosis of the type of pancreatic disease nor do they serve to indicate the severity of the process; that normal values do not rule out pancreatitis since normal values may be obtained when extensive destruction of the acinar cells has occurred; that clinical symptoms and clinical signs must be used in conjunction with these tests in arriving at a clinical diagnosis of the type of disease that is present in the pancreas.

The determinations both of lipase and of amylase in the serum have their own advantages. Thus, amylase determinations can be done within the hour while that for lipase requires twenty-four hours. On the other

hand, elevated values for lipase are associated more frequently with malignant disease of the pancreas than are elevated values for amylase, and the elevations for lipase in acute inflammation of the gland persist for a longer period of time than do elevated values for amylase. Elevated values for lipase in association with hepatic disease sometimes may confuse the diagnosis, but this should not be the case if the elevations in the value for this enzyme are always interpreted in the light of historical, clinical and other laboratory data.

TESTS FOR DISTURBANCES OF INTERNAL SECRETION OF ISLANDS OF LANGERHANS

Disturbed Secretion of the Hormone of Carbohydrate Metabolism.—The hormone insulin, concerned in carbohydrate metabolism, is probably secreted by the beta cells of the islands of Langerhans, and tests for disturbance of its secretion in common use in the diagnosis of diabetes mellitus may also be used in the study of disturbances of this secretion in the presence of other diseases of the pancreas. Glycosuria has been reported in from 5 to 20 per cent of cases of acute pancreatitis²⁸ and occurred more frequently in the severe cases. Hyperglycemia has been encountered in 50 per cent or more of the cases of acute pancreatitis²⁹ and occurred more frequently in pancreatic necrosis than in acute pancreatic edema. Bernhard³⁰ has expressed the opinion that the test for dextrose tolerance will disclose a disturbance of carbohydrate metabolism in a high percentage of cases of acute pancreatic disease in which glycosuria and hyperglycemia are absent. He also has said that the test for dextrose tolerance discloses mild disturbance of carbohydrate metabolism in the presence of pancreatic edema and discloses severe disturbances in cases of pancreatic necrosis. The test thus serves to distinguish between the two types of acute pancreatic disease. From these reports it would appear that, if preexisting diabetes can be excluded, glycosuria, hyperglycemia and disturbed tolerance for dextrose should point definitely to pancreatic inflammation if found during an attack of upper abdominal pain. However, in view of the readiness with which glycosuria, disturbances of concentrations of sugar in the blood and disturbances of tolerance for dextrose occur in association with infections, in attacks of cholecystitis and even in coronary thrombosis,³¹ fasting concentrations of sugar in the blood (less than from 175 to 200 mg. per hundred cubic centimeters) and tests showing disturbance of tolerance for dextrose should be interpreted with extreme conservatism.

ally experiences hypolipemia and marked fatty metamorphosis together with impaired function of the liver, diminished excretion of dextrose and a marked sensitivity to insulin. In 1936 Dragstedt, van Prohaska and Harms³² presented evidence that these changes were due to a deficiency of a hitherto undescribed internal secretion manufactured by the pancreas. They suggested the name "lipocaic" for this substance, which they assumed had to do in a general way with utilization of fat and they prepared an extract of the pancreas that would reverse these changes in the liver and increase the concentration of blood fats. Ivy and Gray³³ in 1939 concluded, however, after a review of the facts pro and con, that the evidence supporting the view that lipocaic is an internal secretion of the pancreas is by no means complete but that the evidence that lipocaic is not choline and that it is effective in preventing a deposition of fat in the liver of depancreatized dogs is very convincing. The experiments of Bensley and Woerner³⁴ would indicate that the alpha cells of the islands of Langerhans secrete the substance concerned with fat metabolism. Reports indicate that deficiency of the secretion of the hormone dealing with metabolism of fat has been encountered in cases of pancreatitis and among diabetic patients.³⁵ In these cases, bromsulphalein and hippuric acid tests have disclosed disturbances of hepatic function. Changes in blood cholesterol levels have also been observed.

COMMENT

We may safely conclude that tests exist whereby the functions of the different types of cells of the pancreas may be adequately studied.

The determination of the volume of duodenal content, its p_H values, the concentration and total excretion of bicarbonate and enzymes per unit of time after stimulation of the pancreas with purified secretin and mecholyl chloride, all constitute an especially promising group of tests of external function of acinar cells and are especially useful in cases of pancreatitis after the acute phase has passed, in cases of chronic sclerosing pancreatitis and malignant disease of the pancreas.

Measurement of the values for lipase and amylase in the serum and urine is very useful for detecting functional alterations of acinar cells due to either inflammation of the gland or obstruction of the pancreatic duct.

Determination of values for sugar in the urine and in the blood and of the tolerance for dextrose supplies trustworthy information about the secretory disturbances of the islands of Langerhans in cases of pancreatitis, provided that preexisting diabetes can be excluded.

It is emphasized that these tests are tests of pancreatic function. The results of such tests do not in themselves indicate the type or the degree of the pathologic change present in the pancreas. On the contrary, the type of pancreatic disease present and its degree of severity must be decided on the basis of the history, physical conditions and the results of other laboratory examinations.

STUDIES IN OLD AGE

IV. THE CLINICAL SIGNIFICANCE OF SALIVARY, GASTRIC AND PANCREATIC SECRETION IN THE AGED

JACOB MEYER, M.D.

AND

HEINRICH NECHELES, M.D., Ph.D.

CHICAGO

The digestion of the aged has received but little attention in the literature. There is, however, a common belief among the medical profession and the public that disturbances of digestion are associated with a faulty dietary, and restriction of diet and special diets have therefore been the vogue for the aged. Much of what is accepted seems to be based on fear and habit rather than on basic experimental observations.

It is also known that gastrointestinal symptoms are common in the aged while organic diseases of the gastrointestinal tract are relatively uncommon. According to Rivers,¹ indigestion is a complaint of half of the patients between the ages of 30 and 60, and Barker² and his associates have studied the case histories of 300 patients past 60 years of age and noted that digestive symptoms were second highest in frequency; they found that despite the high incidence of digestive symptoms in this group there were only three cases of gallbladder disease, two of ulcer of the pylorus and two of ulcer of the duodenum. It is generally recognized that, in the aged, gastrointestinal symptoms may often be due to diseases outside the alimentary tract, as for example cardiac, renal, arthritic and hematologic disease.

Digestive disturbances, however, which may result from physiologic changes in the gastrointestinal tract, accompanying the aging process, are not clearly defined.

Observations in Two Age Groups

Age		Basal Secretion				Stimulated Secretion			
		Ptyalin Concentration				Ptyalin			
Years	Average	Number of Subjects	Variation	Average	Volume, Cc.	Average	Variation	Average	Specific Gravity
21-31	25	12	2.4-22.2	10.15	13.6-15	14.2	2.14-3	8.2	1.001
60-100	81	27	0.19-0.48	0.303	1.5-15	5.8	0.18-0.42	0.28	1.009

We therefore undertook a study of the secretion of the aged in order to establish what is normal and also to clarify the relationship which may exist between the secretory changes in the aged and clinical symptoms.³

We studied the basal (fasting) secretion of saliva and the secretion of saliva after a stimulus (chewing). Chart 1 illustrates the basal secretion of salivary amylase in thirty-two persons from 12 to 60 years of age and in twenty-nine persons from 60 to 90 years of age.⁴ The results in part A of chart 1 demonstrate the forma-

tion of maltose from starch (end point method) and in part B the formation of dextrin from starch by salivary amylase. The latter method shows the intermediary products of digestion of starch by saliva, and the results obtained are of importance because only part of the starch ingested is digested completely (i. e. to maltose) in the mouth and stomach. The results demonstrate that the conversion of carbohydrates by salivary amylase to maltose and dextrin is markedly depressed in the aged, and particularly the formation of dextrin. Thus the first stage of starch digestion is severely depressed while complete digestion of starch is considerably diminished. This confirms previous work⁵ in which volume, and ptyalin content of stimulated salivary secretion was investigated, only the Wohlgemuth method (dextrin) being used.

The values found in this work were lower than those reported before, but different groups of subjects were employed, of different stock and on different nutrition. We are therefore of the opinion that there is a marked

in younger persons, occurring mainly after stimulation by a meal.

Our conclusion from this study is that in old people carbohydrate digestion is probably completed in the intestinal tract and that the pancreatic amylase is a substitute for the salivary amylase.

Chart 2.—Pancreatic amylase. This graph is rather similar to chart 1 A, except that the units are much less. It is obvious from the chart that the aged need suffer no embarrassment of carbohydrate digestion.

Chart 1.—A, salivary ptyalin estimated by the Shaw and Ross method. The enzyme activity falls little in the older age groups, although a downward trend is evident. The reaction is carried to completion, i. e. to the formation of maltose. B, salivary ptyalin estimated by the Wohlgemuth method. The concentration of ptyalin falls markedly about the sixtieth year of life. This reaction involves only the first step in the breakdown of starch to achroodextrin (amylolastic action).

decrease or incomplete digestion of carbohydrates in the mouth and to a certain degree in the stomach of old people. Old people eat a considerable amount of carbohydrate foods because they are easier to chew and because in institutions for the aged carbohydrates comprise a greater portion of the diet. We expected to find evidence of incomplete carbohydrate digestion. It is of interest, however, that old people seldom complain of symptoms indicating incomplete carbohydrate digestion. These clinical observations are explained by our later investigations⁶ in which we studied the pancreatic secretion of old people and discovered that stimulated pancreatic amylase is present in normal amounts while the amylase in the fasting duodenal juice is lower than in young people. This fact seems to indicate that in old people pancreatic secretion is more intermittent than

The dry tongue of old age may be explained by the decreased quantity of salivary secretion. The diminution of body fluids and the changes in blood chemistry may likewise be an important factor.

The tongue of the aged is often a difficult problem from a diagnostic and therapeutic aspect. It is important to differentiate the dry tongue due to metabolic disturbances and that due to such clinical entities as the anemia of the aged, achlorhydria, vitamin deficiency, Plummer Vinson's syndrome, pernicious anemia and psychogenic factors. Ivy⁷ states that the atrophic changes of the mucosa of the tongue are more frequent in the elderly people with achlorhydria than in those with gastric acidity.⁸ According to Hutter and Middleton⁹ the atrophic changes of the tongue are more related to dietary deficiency than to achlorhydria. It is very likely that both achlorhydria and diet are involved.

It has been established by numerous investigations that the incidence of achlorhydria increases with advancing age. There is much discussion as to whether

Chart 3.—Pepsin. The concentration falls sharply during the seventh decade of life and after that maintains a rather constant low value.

achlorhydria is due to a chronic gastritis, to an inherited predisposition or to a physiologic involution associated with senile atrophy. We determined the values for free

acid in the fasting gastric juice of twenty-nine patients between the ages of 60 and 96. In approximately 65 per cent of these aged subjects there was no free acid in the fasting contents, while in 35 per cent of the younger subjects there was also no free acid in the fasting contents. We likewise made determinations of

Chart 4.—Appetite secretion in a group of twenty-six subjects from 18 to 45 years of age (Y) and a group of nine subjects from 50 to 62 years of age (O), average 32 and 55 years respectively.

the secretion of pepsin decreased in age as much as does the secretion of acid.

In view of the importance of psychic secretion of the stomach for appetite and digestion it is of interest to see whether this is changed in old people. The data obtained in previous work by one of us¹¹ were therefore regrouped and charted according to age and are presented in chart 4. It shows that the free acidity of gastric juice following the chewing of chilled orange (nothing was swallowed) drops considerably in the old people ten minutes after stimulation, while in the younger group it rises at the same interval. After that both curves rise and the two are similar. The total acidity is roughly the same in the two groups, only slightly lower in the older people. The drop in free acidity is explained by greatly increased volume of secretion in the older group ten minutes after stimulation. This shows that the drop in free acidity was due to dilution by a fluid containing combined but no free acid.

The concentration of trypsin in our study is similar to that of pancreatic amylase. The fasting duodenal contents show a decidedly lower level in the aged, while

the concentration of pepsin. We found a steady drop in the concentration of pepsin during the seventh decade of life, and after that age the concentration maintained a constant low value. We could find no correlation between the concentration of the acid and pepsin in the fasting gastric juice.

Chart 3 indicates the low values for pepsin in old people. It also demonstrates that in the younger group there is greater variability in the pepsin concentration than in the group of old persons, in which it is relatively constant. Osterberg, Vanzant, Alvarez and Rivers¹⁰ made an analysis of the gastric juice of 6,200 patients and our observations parallel theirs closely in that the values for pepsin fluctuate widely in the case of young persons. These authors also found that after an Ewald meal

the stimulated pancreatic juice has the same concentration of trypsin in the old as in the younger group.

In spite of the low concentration of pepsin and trypsin, nothing has been written about special difficulties of old people for the digestion of proteins. It is likely that tryptic and peptic digestion in the intestine and possibly in the stomach (regurgitation) is adequate to meet the requirements of a small protein intake. We are, however, aware that there are old persons whose protein intake is fairly large who have no difficulties of digestion.

Lipase in the fasting duodenal contents and in the stimulated pancreatic secretion was distinctly lower in the old group as compared to the younger group, the difference being approximately 20 per cent. In view of the biologic reserve in all secretion this may not mean impaired digestion of fats except possibly when too much fat is ingested at one time.

The restrictions in diet, particularly restrictions of protein which are often self imposed or imposed by an overanxious or overprotective physician or family, are perhaps unwarranted in the light of our observation. With few exceptions the majority of old people select both quantity and quality of their foods which satisfy their needs and tastes. The family physician will do well to allow the aged to follow this "natural selection." It may be that the aged, just as children and animals, select foods which their organism requires.

The secretory changes which we have observed may be attributed to a gastritis rather than to the normal involution of old age. This is a most difficult problem to answer definitely. We are aware that in many people there may be no secretory change. We are likewise aware that these secretory changes may occur without any symptoms. Bloomfield noted changes in secretion with advance in years in some patients, while in others it remained unaltered. These observations likewise do not offer a solution for the changes in secretion in one group as contrasted with the apparently normal state of the secretion in others. It is necessary to make combined gastroscopic studies and secretory studies in old people to elucidate this problem further. Schindler's observations on atrophic gastritis would seem to indicate that in the aged the secretory changes are associated

Chart 5.—Trypsin. The tryptic activity falls sharply after the fortieth year of life. The proteolytic powers of pancreatic juice bear no relation to gastric acidity.

with a gastritis. However, our own concept is that the process is probably an involutionary change.

It is possible that the quality of the food may be a factor in the secretory response. In deficiency diseases such as a vitamin B₁ deficiency there are changes in gastrointestinal secretions and motility. We therefore have made some preliminary observations on the rela-

tionship of vitamin B₁ to the achlorhydria of the aged.¹² We studied thirty-six patients between the ages of 52 and 80 who had achlorhydria to histamine and who presented no gastrointestinal symptoms; nor was there any evidence of vitamin deficiency to indicate that we were dealing with pellagra or pernicious anemia. Nine of these patients were given 15 mg. of thiamine hydrochloride hypodermically for fifteen days. No changes were observed in the free or total acidity as a result of this treatment. Nine patients were given 10 Gm. of brewers' yeast daily for a period of fourteen days and no notable change in free or total acidity was observed.

Chart 6.—Pancreatic lipase. The lipolytic activity of pancreatic juice is variable and is dependent neither on gastric acidity nor on the age of the subject.

The problem of appetite in the aged raises numerous questions. Carlson¹³ quotes Sternberg as saying that the "appetite is in some way associated with the tonus of the muscles of mastication and deglutition and the absence of appetite and the nausea is due to atony of these muscles." In the aged it is common to observe changes in the tonus of the musculature of the mouth, and appetite may be absent and nausea may or may not be a complaint. Carlson states that "a certain sensation complex from the viscera and a normal state of central correlation as a necessary background for appetite. Given this background the essential in appetite is the memory process of past experience, sight, smell and taste with palatable foods. These memories are reinforced by present stimulation of these nerves by food." Visual disturbances and changes which are said to occur in the taste buds and in the sense of smell in the aged may explain the absence or diminution of appetite in old people. Certainly the role of the memory process in the aged must be considered an important factor in relation to appetite. Additional factors, as the salivary and gastric secretion and the change in hunger contractions, undoubtedly play an important role in the appetite mechanism. It is important for the clinician to be familiar with the factors concerned in "appetite," particularly as it relates to old people. The older therapeutic measures such as wines, alcohol and bitters are said to be effective. Recent clinical experience shows that vitamin B is likewise of value in stimulating the appetite. While our observations indicate that vitamin B may not increase the gastric acidity in patients with achlorhydria, it may be effective in instances of lowered acidity, or again it is likely that vitamin B increases appetite by shortening the emptying time of the stomach.

We wish to draw attention to the occurrence of acute peptic ulcer in the aged. It is generally believed that gastric and duodenal ulcer rarely occur in the aged and, if so, on the basis of arteriosclerosis of the gastric blood vessels. Our experience has been that ulcer is more frequent in the aged as a primary acute lesion than is generally recognized and that it is often present as a secondary disease, i. e. secondary to diseases of liver, kidney, heart or prostate. The general theory as to the genesis of ulcer presumes the presence of hyperacidity, but the relative frequency of achlorhydria or low values of acidity suggest that in the aged there may be other factors than the corrosive action of hydrochloric acid and pepsin responsible for the genesis of peptic ulcer. A gastritis in the aged as being an important factor in the etiology of ulcer is readily conceivable, because the diminution or absence of free acid permits the activity of bacteria to precipitate the ulcer process.

The frequency of perforation of peptic ulcer in the aged is also not readily explained. If the progress and activity of an ulcer are dependent on the digestive action of free hydrochloric acid and pepsin, one would expect fewer perforations because of the diminution of acid and enzymes. The occurrence of a fairly large percentage of perforations would indicate that there may be other factors which give rise to perforation in the aged.

SUMMARY

1. Gastrointestinal symptoms are common in old age, but gastrointestinal disease is relatively uncommon.
2. Old people show changes in the salivary, gastric and pancreatic secretion (except amylase), all of which are a decrease in the quantity of secretion and enzymes.
3. The diminution in the quantity of secretion apparently does not affect intestinal digestion.
4. Despite the diminution in the secretion, the secretory mechanism is capable of response under adequate stimulation.
5. Restrictions imposed on old people because of fear of inadequate digestion of carbohydrate, protein and fat do not appear warranted.
6. Acute peptic ulcer with severe complications occurs in old people in association with cardiac, renal, hepatic and prostate disease.

55 East Washington Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. COMFORT AND DRS. MEYER AND NECHIELES

DR. JOSEPH S. DIAMOND, New York: The older methods of studying the external secretion of the pancreas presented many difficulties. The use of food as a stimulus, the admixture of gastric chyme and the lowered pH values prevented one from obtaining accurate determinations of the functional activity of the gland. With the introduction of a purified secretin and the use of the double lumen gastroduodenal tube these difficulties have been overcome. Secretin is a potent pancreatic stimulus which is used parenterally in standard dosage. The separate collection of duodenal and gastric juices enables one to obtain a clear, uncontaminated pancreatic juice. The withdrawal of the juices under gentle suction supplies one with the total output of the secretion of the gland for a given time, for the complete quantitative study of the volume, alkalinity and the enzymes amylase, trypsin and lipase. The volume of pancreatic juice collected following the secretin injection varies between 135 and 250 cc. and is rich in bicarbonate and all the enzymes. Physiologically the secretion of the pancreas is controlled by a neuro-hormonal mechanism. The volume and bicarbonate are directly proportional to the hormone secretin, while the enzymes are dependent in addition to the vagal tone. When vagal stimulants

such as insulin and acetylcholine are used in conjunction with secretin the concentration of the enzymes is increased from two to three fold, while the volume and bicarbonate remain unchanged. Dr. Comfort has used mecholyl while I have used insulin, injecting 16 units intravenously one half hour before secretion. In pathologic states of the pancreas the enzymes become affected first, bicarbonate last of all. The enzymes may become dissociated so that one may be affected more than another. In severe lesions all functions are simultaneously affected. I have been working with secretin since 1938. Dr. Siegel and I have performed by now 130 tests in 104 individuals, of whom twenty-four were normal and eighty pathologic. The test has helped us to discover lesions of the pancreas in many instances in which it was least suspected. In cases of painless jaundice, with identical clinical pictures of obstructive jaundice, the test has helped us differentiate a carcinoma of the head of the pancreas from a primary lesion of the common bile duct. In acute hemorrhagic pancreatitis the test revealed a very marked depression in all the functions, showing but little recovery even as late as ten months after the operation. In a group of cases of steatorrhea we were able to differentiate the idiopathic forms from those having pancreatic disturbances.

DR. A. C. IVY, Chicago: I should like to commend Dr. Meyer and Dr. Necheles and their associates for the type of work they have been doing. The physiology of digestion of the infant and child has been placed on a sound basis by experimental and clinical investigation. In the field of geriatrics the physiology of digestion will be placed on a sound basis only by experimental and clinical investigation. Considerable information is available concerning the physiology of digestion in the infant, the child and the adult, but there is little information regarding that subject in the aged. If present population trends continue, the subject of geriatrics is likely to become as important as the subject of pediatrics is today. I should like to recommend that they continue their study on the enzymes to include studies on motor activity and then to study the coefficient of digestion of foods. The coefficient of digestion is the principal subject of interest. One should be interested not only in the enzymes that are secreted but also in the motor and the absorptive activity. By knowing the intake of protein, fat and carbohydrate and by analyzing the feces, one can determine the extent to which protein, fat and carbohydrate are being digested and absorbed. I should like to emphasize the importance of stool analysis. I have met gastro-enterologists who have forgotten the importance of stool analysis. When one performs the "new secretin" tests one should correlate the results with stool analysis. One should not be misled by the results of a study of the enzyme output of the pancreas, as occurred a number of years ago by a fractional study of the acidity of gastric contents, forgetting to study and pay close attention to the stools.

DR. EDWARD S. EMERY JR., Boston: It is a common experience to encounter elderly persons with gastrointestinal disturbances. The symptoms vary widely and are frequently similar to those accompanying organic disease in younger persons. Although it cannot be said that there are gastrointestinal symptoms of old age which are characteristic diagnostically, certain traits of behavior occur frequently enough to justify comment. Often the symptoms are intermittent, disappearing and returning for no apparent reason. Many notice a decreased appetite which their physicians attribute to a sedentary existence. Others find that their desire to eat is as good as formerly but that they are no longer able to take large meals without distress. With these patients the kind of food appears to be of less importance than the amount. Still others have a normal appetite for breakfast, whereas they have little desire for food the rest of the day. These patients find that their appetite is a good index of how well their stomach tolerates food. The "digestion" of old persons is influenced strongly by fatigue, which undoubtedly explains many of the apparent vagaries in the general behavior of their symptoms. This striking influence of fatigue would seem to be explained by the decreased enzymatic concentrations which are reported by Dr. Meyer and Dr. Necheles, because their studies suggest that the digestive ferments of the saliva and stomach are reduced in old age. Presumably the elderly cannot make secretions as rapidly as the younger person. It is interesting to know that the older pancreas responds to stimulation like the

younger one. I have just reported before the American Gastro-Enterological Association the results of some studies on the enzymes of the upper jejunum made at the Peter Bent Brigham Hospital during the past year. The striking lesson from these studies is the rapidity with which the enzymes regain their normal concentration after their equilibrium has been disturbed. There was some reason to believe that the pancreas might help to readjust this disturbance. The indigestion of age is explained better by a diminution in the amounts of enzymes secreted than by the sedentary existence of these patients. Also it may explain the greater susceptibility to physical fatigue of the older digestive tract. If digestion is adequate only for breakfast, this may be due to storage of digestive elements during the night, permitting a sufficient amount for this meal but an inability to make ferments fast enough to take care of the noon and evening meals.

DR. JOHN L. KANTOR, New York: May I emphasize what Dr. Ivy has said? The clinician, in studying the work of the pancreas, must investigate the stools for his final appraisal. A. J. Carlson voiced this thought about ten years ago, and five years ago it was stressed by Dr. Pratt of Boston. The secretion of the pancreas supplies three important ferments. As far as the amylase is concerned, it must be admitted that there is no clinically effective method of studying the result of carbohydrate digestion in the stool. When it comes to the work of trypsin, that is, digestion of proteins, one can study the nitrogen, although I suppose that the effect of pepsin must also be considered. There are certain standard figures that every clinician interested in this field should try to carry in mind. First there is the total fecal fat, which should not exceed 20 per cent of the weight of the dried stool in the normal individual. Then there is the fat loss, which should not exceed from 5 to 7 per cent of the ingested fat. Finally there is the fat split, which should be about 60 to 75 per cent of the total fecal fat. To use these basic figures intelligently, it is desirable that the fat content of the diet be accurately established. Any diet the fat content of which is known can be used, or else one may employ the standard Schmidt intestinal test diet. When milk is given with this diet, the quantity of fat is about 142 Gm. daily; when cocoa is used instead of milk the daily intake of fat is about 112 Gm. A good plan is to administer this weighed diet for three or four days and to collect and analyze the stools of the last two days for their fat values.

DR. HEINRICH NECHELES, Chicago: I should like to say a few words of caution about secretin. The preparation available for intravenous injection in man deteriorates and becomes toxic on standing, as we found in assays carried out over a period of time; it is rather expensive besides. I assume that the previous speakers employed secretin Astra, the Swedish preparation. Furthermore, I believe that the secretin test cannot be interpreted easily. Secretin produces a water secretion of the pancreas containing largely bicarbonates. It seems that the increase in ferments reported by various workers is due primarily to a washing out effect and not to true secretion. It would seem better, therefore, to combine secretin with physostigmine or prostigmine as we have done, or with mecholyl, as has been reported just now. I believe even that secretin is not necessary because we get a response with mecholyl alone. I believe, however, that 15 mg. of mecholyl is a very large dose even for a normal, healthy adult, as we have experienced a number of times. Trypsin seems to be the only ferment in the small intestine that can be identified as of strictly pancreatic origin, and as long as so little is known about duodenal and upper jejunal secretions it is dangerous to conclude from a diminution of lipase and amylase that this is necessarily due to deficiency of pancreatic secretion. It might well be that a slight duodenitis will increase the output of lipase and amylase by the duodenal mucosa. Also when one collects duodenal juice following secretin one must express pancreatic secretion not by the concentration but by the total amount of enzymes. Pancreatic secretion ought to be collected quantitatively and this is extremely difficult, even with a Miller-Abbott tube. The considerable increase in the volume of psychic gastric secretion of old people surprised us. In a recent paper Bloomfield reported that he found no relation of psychic secretion to age. I recalculated his values and found that the volume increase for psychic secretion was 9 cc. for

young and 23 cc. for old persons. This confirms our results. It seems thus that in old persons the vagal secretory gastric mechanism is unimpaired and may even be more responsive than in young persons.

DR. MANDRED W. COMFORT, Rochester, Minn.: Considerable emphasis has been placed by various discussers this morning on examination of stools as a procedure of choice for studying pancreatic function. I agree that the analysis of stools for undigested and unabsorbed foodstuffs gives excellent data about the completeness of digestion, but I do not believe that the data obtained from the study of stools necessarily disclose the true status of the external secretion of the pancreas, since the small bowel may assume part of the digestive functions of the pancreas. Moreover, from the results of examination of stools for undigested and unabsorbed foodstuffs it is not often possible to distinguish disturbances of digestion secondary to pancreatic disease from those secondary to disease of absorption. Thaysen, a Copenhagen investigator, expressed the belief that the loss of more than from 35 to 40 per cent of ingested fat as neutral fat and the loss of more than 3 Gm. of nitrogen in the stools daily are the only observations from the stools which are of significance in the diagnosis of pancreatic disease. Dr. Necheles has brought up the question of reactions. I have given approximately sixty injections of secretin without a single reaction and Dr. Diamond tells me that he has not had a reaction in about 130 experiments. Acetyl-beta-methylcholine chloride (mecholy) in doses of 15 mg. subcutaneously produces considerable discomfort and marked sweating. Patients have not objected to this reaction when they have been warned of it in advance and know what to expect. The technic of removal of the duodenal contents has been criticized. It is certainly true that possibilities of error are inherent in the method but it is the best technic that has been described so far for removal of the duodenal contents. These various methods of studying the function of the cells of the pancreas which produce the external secretion need much further use before final evaluation of their merit can be made. Ten years ago, histamine was considered by some workers to be a stimulant of gastric secretion that would produce a constant and maximal response. Today we know that histamine has not measured up to the earlier expectations. As time goes on we may find that secretin, acetyl-beta-methylcholine chloride and allied drugs have certain disadvantages; but I am sure also that they will possess considerable merit for use in the study of pancreatic secretion.

DR. JACOB MEYER, Chicago: We have been impressed for a number of years with the importance of physiologic studies such as Dr. Ivy has mentioned in order to interpret and evaluate the clinical symptomatology. Much of what he has suggested has been planned, and some of the work is in progress. We likewise have been impressed with the growing significance of old age not only as a social problem but also as a clinical problem, and gastro-enterologists particularly should be cognizant of the manifold problems which are to come to us for solution in the very near future. Dr. Aaron's observation and criticism in a sense is a fair one, but what he has said holds true for almost any type of secretory test on any individual. We recognize the variations in individuals and we must recognize the various factors which may produce these variations. We are not presenting our results as indicating any specific test. We are primarily interested in presenting what is normal for old persons. I should like to call attention to the fact that while the criticism which he has mentioned applies to the individual, statistical analysis of a group of individuals is probably the best means of determining what is normal.

Disinfection.—Destruction of the infecting organism is a logical step in preventing the spread of disease. Concurrent disinfection is the most important of the disinfection procedures. It simply represents an immediate and proper disposal of all the excretions of the patient. Terminal disinfection is essentially a question of cleanliness and is brought about by soap, water and sunshine. Terminal gaseous disinfection has been abandoned, except for destruction of insects and vermin.—Smillie, Wilson G.: Public Health Administration in the United States, New York, Macmillan Company, 1940.

PNEUMOCOCCUS AND HAEMOPHILUS
INFLUENZAE

JOSEPHINE B. NEAL, M.D.
EMANUEL APPELBAUM, M.D.
AND
HENRY W. JACKSON, M.D.
NEW YORK

During a period of nearly thirty years we have been studying the effect of various forms of therapy in bacterial meningitis. Before the newer chemicals became available the case fatality in pneumococcic meningitis was 100 per cent in our experience and in meningitis due to *Haemophilus influenzae* more than 95 per cent.

The use of azosulfamide and sulfanilamide moderately improved the prognosis. In a series of fifty-three cases of pneumococcic meningitis treated by one or both of these chemicals (and specific serum when available) there were nine recoveries. In treating meningitis due to *H. influenzae* by means of these chemicals and specific serum the results were much less encouraging. In a series of twenty-nine cases there were only two recoveries.

The excellent results obtained with sulfapyridine in pneumonia due to the pneumococcus led us to try the use of this chemical in pneumococcic meningitis. This report is based on a series of thirty cases. The diagnosis was definitely established in each instance by culturing and typing the organisms from the spinal fluid.

Table 1 shows the distribution of the cases by sex, the wide range in age and the causative types. These items are self evident. The other data will be discussed.

Blood cultures were obtained in twenty cases. Of these, ten were positive with six deaths and ten negative with five deaths. From these small groups it would appear that the presence of bacteremia had no particular bearing on the outcome.

Consideration of the foci of infection is of the utmost importance. A definite focus in the ear or mastoid or both was found in seventeen of these thirty cases. In three others there was a strong suspicion of such a focus. In one of the cases with otitis (13) there was a petrositis. In two instances there was a fractured skull and in one a head injury with a possible fracture. While this series shows no record of definite sinus involvement, yet in view of the condition found at necropsy it seems reasonable to assume that an undiagnosed involvement of sinuses, particularly the sphenoids and ethmoids, must have been present in a number of these cases. It is highly probable also that in not a few of these cases there were multiple foci of infection.

It will be noted that in these thirty cases there were ten recoveries. In three of the fatal cases death occurred within twenty-four hours after treatment was begun.

Sulfapyridine was given orally to all of these patients. The dose varied from 4 to 8 Gm. daily, usually at intervals of four hours. Young children have as a rule an excellent tolerance, so that a daily dose of from 4 to 6 Gm. is quite safe in children more than 3 years of age. Infants may be given from 2 to 4 Gm.

When the patient was unable to retain oral medication the sulfapyridine was occasionally administered by rectum in the form of an emulsion with sodium bicarbonate and acacia. The rectal dose was usually twice the oral dose.

The introduction of sodium sulfapyridine has been a distinct advantage. We have used a 2 per cent solution of this compound intraspinally, usually combined with a specific serum, in fourteen instances. The dose

only mild to moderate changes in the red or white blood counts. There have been instances with evidence of renal damage, hematuria occasionally and in one case anuria associated with azotemia. It is probable that in this instance the kidney tubules were obstructed by concretions of sulfapyridine crystals, although this was not proved as no necropsy was obtained. A case which is not included in this series showed similar symptoms and at necropsy there was extensive blocking of the

TABLE 1.—Cases of *Pneumococcic Meningitis Treated with Sulfapyridine*

Case	Sex	Age, Years	Type	Blood Culture	Primary Focus	Treatment and Comment	Result
1	♂	27	4	Negative	Head injury ?	Serum, sulfapyridine orally, azosulfamide.....	Died
2	♂	3 mos.	5	Positive	Otitis, mastoiditis	Serum by vein, sulfapyridine orally, mastoidectomy.	Died
3	♀	6	4	Positive	Otitis ?	Serum, sulfapyridine orally for 2 mos.; no effect on blood; had also panophthalmitis; apparent recovery for 2 weeks and then relapse	Died
4	♂	28	18	Negative	None found	Serum by vein, sulfapyridine orally, large doses; rash, and anuria, high urea nitrogen and nonprotein nitrogen; albumin and red blood cells in urine	Died
5	♂	8	18	Negative	Otitis, mastoiditis	Mastoidectomy, sulfanilamide and azosulfamide; sulfapyridine orally	Recovered
6	♀	50	1	Otitis, mastoiditis	Mastoidectomy, serum, sulfapyridine; died within 24 hours after treatment was begun	Died
7	♂	11	5	Positive	Otitis, mastoiditis	Mastoidectomy, serum by vein and intraspinally; sulfapyridine; red blood cells and sulfapyridine crystals in urine	Recovered
8	♂	13	5	Positive	Upper respiratory infection	Serum by vein, sulfapyridine.....	Recovered
9	♂	1½	4	Positive	Otitis, brain abscess	Brain abscess drained, serum by vein and intraspinally; sulfapyridine	Recovered
10	♀	26	3	Positive	Otitis, mastoiditis	Mastoidectomy before meningitis; sulfanilamide 11 days, sulfapyridine 1 day	Died
11	♀	39	8	Otitis	Sulfapyridine, serum and sodium sulfapyridine intraspinally; died within 12 hours	Died
12	♀	33	1	Otitis	Sulfapyridine; in seventh month of pregnancy.....	Died
13	♂	48	3	Negative	Otitis, petrositis	Reexploration of petrous bone; serum and sodium sulfapyridine intraspinally; sulfapyridine	Recovered
14	♀	50	3	Negative	Otitis, mastoiditis	Mastoidectomy before meningitis; operation revised later; sulfapyridine, sodium sulfapyridine intraspinally; sinus thrombosis and jugular ligation	Died
15	♀	27	3	Negative	Otitis, mastoiditis	Serum intravenously and intraspinally, with sodium sulfapyridine; sulfapyridine	Died
16	♂	5½ mos.	18	Otitis	Sulfapyridine	Died
17	♂	9	3	Negative	Otitis, mastoiditis	Mastoidectomy; serum and sodium sulfapyridine intraspinally; sulfapyridine	Died
18	♂	14	15	Fractured skull	Sulfapyridine; sodium sulfapyridine intraspinally....	Recovered
19	♂	64	18	Sulfapyridine; sodium sulfapyridine intraspinally; died within 24 hours after treatment	Died
20	♂	58	3	Otitis	Sulfapyridine; sodium sulfapyridine and serum intraspinally; developed pneumonia while under treatment	Died
21	♀	1½	14	Positive	Serum; sulfapyridine; developed brain abscess.....	Died
22	♂	44	1	Negative	Mastoiditis	Mastoidectomy; serum; sulfapyridine.....	Recovered
23	♀	45	19	Positive	Otitis	Serum and sodium sulfapyridine intraspinally; sulfapyridine	Recovered
24	♀	46	Beyond 32	Negative	Sulfapyridine; sodium sulfapyridine intraspinally; prompt improvement; medication stopped; relapsed after 17 days; same treatment resumed	Recovered
25	♀	9	Beyond 32	Azosulfamide 8 days; sulfapyridine.....	Died
26	♂	43	21	Positive	Fractured skull	Serum intravenously; sodium sulfapyridine and serum intraspinally two or three times; sulfapyridine; sodium sulfapyridine intravenously	Died
27	♀	62	7	Otitis, mastoiditis	Mastoidectomy; serum and sodium sulfapyridine intraspinally; sulfapyridine; bronchopneumonia	Died
28	♀	8	4	Serum and sodium sulfapyridine intraspinally; sulfapyridine	Recovered
29	♀	1 yr. 11 mos.	4	Positive	Mastoiditis ?	Serum and sodium sulfapyridine intraspinally; serum intramuscularly; sulfapyridine	Died
30	♀	48	1	Negative	Mastoiditis ?	Serum intravenously; sulfapyridine; sodium sulfapyridine intraspinally	Died

Thirty cases; ten recoveries; three patients died within twenty-four hours after treatment was begun.

has been from 10 to 15 cc. after each spinal drainage. We have felt that the intrathecal use of this drug was beneficial. No untoward reactions have followed the administration in this dilution. More concentrated solutions should not be used, as there may be dangerous reactions.

The intravenous use of this compound is indicated particularly when the patients are unable to retain oral medication. In this series the sodium compound was used intravenously in only one instance. However, it was used in seven cases of meningitis due to *H. influenzae* and in other cases the data of which have not as yet been correlated.

The toxic effects of sulfapyridine are too well known to require detailed comment. We have encountered

pelvis, calices and tubules with the sulfapyridine crystals. In this particular instance the blood sulfapyridine level was low, averaging 2 mg. per hundred cubic centimeters in spite of the ingestion of large doses of the drug. No doubt the patient was acetylating most of the sulfapyridine.

Serum has been used in addition to sulfapyridine intraspinally in most instances and occasionally intravenously. The intraspinal dose was from 10,000 to 20,000 units following each lumbar puncture. The intravenous dose varied from 100,000 to 300,000 units.

The importance of the eradication by surgery of foci of infection cannot be overemphasized. The nature of these foci has already been discussed. In our experience it is much more difficult to localize and to eradicate

foci of infection in pneumococcic than in streptococcic meningitis. It is also our impression that multiple foci are more common in pneumococcic meningitis. We believe the difficulty in completely eradicating foci of infection is a factor in the less favorable case fatality in pneumococcic meningitis.

The discouraging results with sulfanilamide and azosulfamide in the treatment of meningitis due to *H. influenzae* prompted us to change to sulfapyridine and its sodium salt.

to search for possible foci of infection. In three of our patients with recovery a mastoiditis was present and a mastoidectomy was performed. Another patient with clinical mastoiditis was not operated on and died. There were two patients with ethmoiditis that were operated on and recovered. Unfortunately the material removed at operation was not cultured. One fatal case followed an operation on the palate. In one patient who recovered, the meningitis was preceded by injury and infection of the orbit.

TABLE 2.—Cases of *Haemophilus Influenzae* Meningitis Treated with Sulfapyridine

Case	Sex	Age, Years	Blood Culture	Treatment	Result	Comment
1	♀	5	Serum; sulfanilamide; mastoidectomy, dural slit; sulfapyridine	Recovered	Otitis, mastoiditis
2	♀	1½	Positive	Serum, also intramuscularly; sulfanilamide; sulfapyridine	Died	Necropsy: diffuse meningitis; temporal lobe abscess
3	♂	16	Negative	Serum; azosulfamide; later sulfapyridine.....	Recovered	
4	♂	2½	Negative	Sulfapyridine	Recovered	Injury and infection of orbit; relapse
5	♀	2½	Negative	Sulfanilamide; sulfapyridine	Died	Followed operation on palate
6	♀	7	Positive	Serum; sulfanilamide and azosulfamide; sulfapyridine; sodium sulfapyridine intraspinally	Died	Upper respiratory infection
7	♀	2	Negative	Sulfapyridine	Recovered	Prompt recovery; one positive spinal fluid culture
8	♂	51	Negative	Sulfanilamide and azosulfamide; sulfapyridine; serum and sodium sulfapyridine intraspinally	Recovered	
9	♂	9½	Negative	Sulfapyridine; sodium sulfapyridine; serum intraspinally	Died	Began as brain abscess; operation; necropsy, large brain abscess
10	♂	2¼	Positive	Azosulfamide; sulfapyridine; rabbit serum intraspinally	Died	Upper respiratory infection; otitis
11	♀	4	Negative	Mastoidectomy; azosulfamide; sulfapyridine; serum and sodium sulfapyridine intraspinally	Recovered	X-ray examination showed mastoiditis
12	♂	1	Negative	Sulfanilamide, azosulfamide; sulfapyridine and serum intraspinally; serum in vein	Died	Necropsy: diffuse meningitis; block
13	♂	3	Negative	Sulfapyridine; sodium sulfapyridine intraspinally...	Recovered	
14	♂	3	Positive	Sulfapyridine; serum and sodium sulfapyridine intraspinally	Died	Block
15	♀	1¼	Positive	Fothergill's serum plus complement; sodium sulfapyridine intraspinally; sulfapyridine	Died	
16	♂	3	Positive	Sulfanilamide; sulfapyridine; sodium sulfapyridine and serum intraspinally	Recovered	
17	♂	1½	Negative	Sulfapyridine; sodium sulfapyridine and serum intraspinally	Died	
18	♂	3	Negative	Sulfanilamide; sulfapyridine; sodium sulfapyridine in vein; sodium sulfapyridine with and without serum intraspinally	Died	
19	♀	4	Negative	Sulfapyridine; sodium sulfapyridine in vein.....	Recovered	Responded within 3 days
20	♀	2	Positive	Sulfapyridine; sodium sulfapyridine intraspinally and in vein	Died	Diagnosis made 2 weeks after onset
21	♂	3	Sulfapyridine orally; inadequate dose; sodium sulfapyridine intravenously	Died	Double otitis media and clinical mastoiditis; no operation
22	♀	5½	Negative	Sulfapyridine orally; sodium sulfapyridine and serum intraspinally; mastoidectomy	Recovered	Relapse; otitis, mastoiditis
23	♂	1 yr. 1 mo.	Negative	Sulfapyridine orally; sodium sulfapyridine and serum intraspinally	Died	Block
24	♂	4	Negative	Sulfapyridine orally; sodium sulfapyridine intravenously	Recovered	No treatment intraspinally
25	♀	9 mos.	Negative	Sulfapyridine orally; sodium sulfapyridine intravenously and intraspinally; small amount of serum intraspinally	Died	
26	♂	22	Sulfapyridine orally; sodium sulfapyridine and serum intraspinally	Recovered	
27	♀	8	Positive	Sulfapyridine orally; sodium sulfapyridine and serum intraspinally; later sulfamethylthiazole orally	Recovered	Ethmoiditis; operation
28	♂	35	Negative	Sulfapyridine orally; sodium sulfapyridine and serum intraspinally	Recovered	Followed submucous resection and ethmoidectomy
29	♀	8 mos.	Negative	Sulfapyridine orally; sodium sulfapyridine and serum intraspinally	Died	

Twenty-nine cases; fourteen recoveries.

We are reporting a series of twenty-nine cases in all of which the diagnosis was definitely established by culturing the organisms from the spinal fluid.

Table 2 shows an analysis of the data with regard to these cases. It will be noted from this table that this form of meningitis is essentially a disease of early childhood, twenty of the patients being less than 5 years of age.

Blood cultures were obtained in twenty-six instances, eight of which were positive. From this small series of cases it would seem that a positive blood culture is an adverse factor in the prognosis, since all but two of the recoveries were in the group with negative blood cultures.

While this form of meningitis appears to be a primary disease in most instances, it is nevertheless important

In this group of twenty-nine cases there were fourteen recoveries. It may be noted that among the fifteen fatal cases there were two with brain abscess, three with block and one in which the diagnosis was made and treatment started after the illness had existed two weeks.

Sulfapyridine and sodium sulfapyridine were administered in much the same manner as described in the treatment of pneumococcic meningitis. In the majority of the cases a specific serum often combined with sodium sulfapyridine was injected intraspinally. It should be noted, however, that sulfapyridine or sodium sulfapyridine or both were used without serum in five of the cases in which recovery occurred.

An endeavor to find a satisfactory method of treating meningitis due to *H. influenzae* is particularly impor-

tant, since for the past several years there has been a sharp increase in the incidence of this disease. This increased prevalence has been noted not only in New York but also in Boston by Fothergill.

SUMMARY

We have presented a series of thirty cases of pneumococcic meningitis with ten recoveries and twenty-nine cases of meningitis due to *H. influenzae* with fourteen recoveries treated with sulfapyridine, its sodium salt or both. A specific serum was usually employed as well. However, we believe, in view of our previous experience, that the lower case fatality in both forms of meningitis is attributable largely to this form of chemotherapy.

NEW CLINICAL ASPECTS OF THE
ANALGESIC ACTION OF
MORPHINE

DONALD SLAUGHTER, M.D.

J. CHARLES PARSONS, M.D.

AND

H. DEANE MUNAL, M.D.

DALLAS, TEXAS

Morphine is considered the best pain relieving drug which the clinician has at his disposal, yet there are elements of tolerance, addiction and gastrointestinal disadvantages to its use. It is common knowledge that the drug often causes undesirable constipation. Further, when morphine is given over long periods of time, tolerance develops, and addiction may be the end result. Treadway¹ reports that of a series of 1,276 morphine addicts 325 attributed their original downfall to medical use of this drug. Other authors give conflicting reports, but it is interesting that Adams² states that in Great Britain all the witnesses called before the Departmental Committee except one considered the medical use of morphine as the immediate exciting cause of addiction in a "considerable proportion of drug habitués." Still another drawback to morphine is the frequent necessity of giving large doses, which more quickly leads to tolerance and addiction.

Much work has been done on producing a chemical which might serve as a substitute for morphine. The most notable is, perhaps, dilaudid hydrochloride (dihydromorphinone hydrochloride). It is recognized that, while dilaudid hydrochloride may have certain advantages over morphine, it does not entirely fulfil the requirements for a perfect substitute. As regards other substitutes, Hayman and Fox³ have reported that pantopon⁴ in comparable doses has no advantages over morphine.

The present report considers the use of prostigmine methylsulfate in combination with morphine in a series of approximately 100 cases.

Prostigmine is the dimethylcarbamic ester of m-oxyphenyltrimethyl ammonium methylsulfate. Pharmacologically it is similar to physostigmine salicylate in that it is a stimulant of the parasympathetics and has the power of inhibiting the cholinesterase. It does have the advantage over physostigmine of showing little, if any,

myotic or untoward cardiac effects and of having greater stimulating action on the small intestine. Recently it has been shown by Schweitzer, Stedman and Wright⁵ that prostigmine methylsulfate is the only therapeutic anticholinesterase drug which has a central depressant effect.

The use of prostigmine methylsulfate in myasthenia gravis is now well accepted. Recently it has been used with apparent success in the treatment of deafness.⁶ Further, its use to treat and prevent postoperative ileus and anuria is well established. The rationale in myasthenia gravis and postoperative use rests on the ability of this drug to protect acetylcholine against being destroyed by cholinesterase. The premise as regards deafness is not, at the moment, perfectly clear.

Since Slaughter and Munsell⁷ recently reported that prostigmine methylsulfate potentiates the action of morphine on pressure-pain in cats, it seemed plausible to try out such a combination on the human being. That prostigmine methylsulfate is a safe drug in itself has been shown by Schwark,⁸ Tietze⁹ and others.

The data on patients was obtained from the Robert B. Green Memorial Hospital at San Antonio, Texas, under the supervision of Dr. Alexander Mileau, and from the Edinburgh County-City Hospital at Edinburgh, Texas, under the direction of Dr. L. M. Southwick.

A critical evaluation was made of the following factors:

1. Study of effects of prostigmine methylsulfate-morphine as to effectiveness on different types of pain.
2. Untoward effects of such a combination of drugs.
3. The use of varying dosage of morphine with prostigmine methylsulfate.
4. Determination as to whether or not the combination of these drugs leads to addiction and whether there are withdrawal symptoms after long usage.
5. The use of prostigmine methylsulfate in treating addiction.

RESULTS OF TREATMENT

The patients in this study roughly fall into six groups: (1) trauma, (2) preoperative sedation, (3) postoperative treatment, (4) coronary occlusion, (5) miscellaneous cases and (6) addiction.

1. *Trauma*.—There were approximately fifty cases in this series. They consisted of trauma due to gunshot wounds, stabbings, fractures (simple and compound) and other types of extensive trauma in which the pain made morphine mandatory. As a rule only 8 mg. of morphine with 1 cc. of a 1:2,000 solution¹⁰ of prostigmine methylsulfate was given subcutaneously. In these patients apparent relief of pain came on in from two to ten minutes. In other accident cases of a similar nature in which only 16 mg. of morphine was administered as much relief from pain was not obtained and the onset of relief was longer, i. e. from six to twenty minutes. These observations were made from the time of the injection to the time the patient expressed real relief from pain and discomfort.

Only one minor, aged 15; received this treatment. He experienced excellent relief and there were no untoward effects.

3. Hayman, J. M., and Fox, Herbert: Comparison of the Analgesic Action of Pantopon and Morphine Sulfate, *J. A. M. A.* **109**: 1813 (Nov. 27) 1937.

4. Pantopon is no longer included in New and Nonofficial Remedies.

2. *Preoperative Sedation.*—There were twenty-five cases in this group. Most of them were gynecologic but five appendectomies were included.

By trial, the administration of 5 mg. of morphine plus prostigmine methylsulfate four hours before surgical operation and repeated one hour before the operation proved unsatisfactory in producing sufficient sedation.

Further trials established the following routine as giving the most adequate preoperative sedation:

1. Phenobarbital 0.2 Gm. the night before operation.
2. Phenobarbital 0.2 Gm. four hours before operation.
3. Morphine 8 mg. plus prostigmine methylsulfate thirty minutes before operation.

This schedule appeared to give as good sedation as substituting 16 mg. of morphine instead of the 8 mg. plus prostigmine methylsulfate. At the time of operation this use of prostigmine methylsulfate did not interfere with any surgical procedure. All appendixes were removed in the gynecologic cases, if present.

3. *Postoperative Relief from Pain.*—All these patients had orders for 8 mg. of morphine plus prostigmine methylsulfate on return from the operating room, to be repeated every three hours for three doses and then "as needed." There were five cases of moderate distention in this series following operation. These were relieved by the insertion of a rectal tube and the administration of 0.5 cc. of a 1:2,000 solution of prostigmine methylsulfate every twenty minutes for two doses and then every two hours for four doses if needed. Only one patient required the use of a Wangenstein suction.

4. *Coronary Occlusion.*—Five patients with conditions diagnosed as coronary occlusion were treated in the emergency room with 8 mg. of morphine plus prostigmine methylsulfate. All received relief within ten minutes. They then were given this combination every three hours "as needed." In none of these cases was it necessary to order additional doses of morphine. Three received this form of treatment until death, i. e. from eight to thirty-six hours. The other two were discharged after a few days of hospitalization on this treatment. Previously such patients had always received 16 mg. of morphine. We felt that the results of the combination were as good as followed the use of larger doses of morphine.

5. *Miscellaneous Cases.*—These included bronchiectasis, delirium tremens, kidney abscesses, nephritic pains and the dressing of painful wounds. They required morphine. A typical case follows: A patient with nephritis suffered extreme lumbar pain which 16 mg. of morphine did not alleviate. The combination of 8 mg. of morphine plus prostigmine methylsulfate gave and maintained comfort.

6. *Addiction.*—Only one case of true addiction is presented. The patient was treated over a period of six weeks. He had urethral calculi with periurethral abscesses.

Six years previously he had gonorrhea, followed in one year by stricture of the urethra. At this time he entered the hospital for a urethrotomy. Soon after this operation, periurethral abscesses and a urethral fistula developed which persisted until the present time. At intervals, urethral calculi complicated the picture. The patient was an ambulance driver who gave no history of any drug habits before the urethrotomy. After operation he was given 10 mg. of morphine for pain relief. It became necessary to increase this dose to 16 mg. of this drug. Shortly the patient became

addicted and took as much as 30 mg. at intervals. Three years of this habit brought his admittance to a government hospital. After the hospital discharged him as cured of the drug habit, his urethral difficulties returned and a physician put him back on morphine for relief of pain. He continued to take 16 mg. of morphine. Six weeks prior to admission to the Robert B. Green Memorial Hospital, with the diagnosis of periurethral abscesses, urethral calculi and urethral fistula, he stated that he was taking 30 mg. of morphine every four hours.

A radical urethroplasty was successfully performed. Postoperatively he was placed on 30 mg. of morphine. Two days later 16 mg. of morphine plus prostigmine methylsulfate apparently satisfied him. Reduction of the dose of morphine to 10 mg. gave excellent results for four days. Further reduction to 8 mg. did not suffice.

During this stage of the treatment he had not been told of the use of prostigmine methylsulfate but did comment that his bowel action had returned to normal. When he was told of this treatment, he cooperated well. The wound had healed after four weeks and the catheter had been withdrawn. Voluntary urination was instituted after two trials. At this time 10 mg. of morphine plus prostigmine methylsulfate was still being given and the patient did very well, complaining only of slight nervousness just before his dose. This procedure continued through the fifth postoperative week.

The sixth week 8 mg. of morphine plus prostigmine methylsulfate was ordered. After the second day of this treatment the patient skipped every other dose without ill effects. He was then discharged to a government hospital for observation.

During the time prostigmine methylsulfate was used with the morphine, no withdrawal symptoms were noted.

COMMENT

This study indicates that one-half the accepted dose of morphine when combined with prostigmine methylsulfate in doses of 0.5 mg. gives as good relief as the larger dose of morphine. There were no side reactions noted. An order for 0.5 mg. of atropine was always written, but it was never needed. No apparent tolerance to morphine when used in this combination becomes evident.

There was one case of ruptured appendicitis complicated by peritonitis in which this combination gave satisfactory results. Saegesser¹¹ has reported the use of prostigmine methylsulfate in a series of approximately thirty cases of peritonitis. He comments on the excellent results and says that the untoward effects in this condition make this drug suitable for use as a prophylactic to lessen the danger of postoperative intestinal atony. In our series of cases there were none which showed ileus or anuria following operation.

In all but two cases the combination of prostigmine methylsulfate and 8 mg. of morphine relieved pain. Twice in this series of 100 cases it was necessary to give 16 mg. of morphine instead of the smaller dose; one was a case of extensive gunshot wounds and one of compound fracture.

While no untoward effects were observed following the use of this combination, it is felt that perhaps shock is a contraindication to the use of prostigmine methylsulfate with morphine.

We feel that combinations of 1 cc. of a 1:2,000 solution of prostigmine methylsulfate plus 8 mg. of

11. Saegesser, M.: Prostigmine "Roche," Schweiz. med. Wchnschr. 63: 366 (April) 1933.

morphine is an efficient pain reliever. Further, it is an excellent preoperative sedative and postoperative analgesic. When used before operation, it definitely minimizes ileus, distention and anuria. Levis and Axelmann¹² believe that without prostigmine methylsulfate from 60 to 75 per cent of patients will suffer from one or the other of these conditions. Used post-operatively, enemas and the use of catheterization are decreased.

The one case of addiction treated with prostigmine methylsulfate lends encouragement to the use of this drug in similar cases.

The results in this study would seem to substantiate the experimental work done on this problem. We believe that they bear out the findings of Slaughter and Munsell⁷ that morphine is a cholinergic drug as regards its action on pain. That it is cholinergic in other respects is evidenced by the reports of Slaughter and Gross¹³ on the dog's intestine, cat's blood pressure and toxicity in rats.

Summary Comparing Analgesic Effects of Morphine Alone and in Combination with Prostigmine Methylsulfate and Phenobarbital

Drug Used	Dose	Time for Onset of Action	Mode of Onset	Duration of Action
1.* Morphine sulfate	16 mg.	6-20 min.	Gradual	60-90 minutes
2.* Morphine sulfate Prostigmine methylsulfate	8 mg. 0.5 mg.	2-10 min.	Increased over 16 mg. of morphine alone	90-120 minutes †
3.† Morphine sulfate Prostigmine methylsulfate	5 mg. 0.5 mg.	6-20 min.	Gradual	30-60 minutes
4.‡ Phenobarbital 4 hrs. before surgery Phenobarbital 1 hr. before surgery Morphine sulfate plus Prostigmine methylsulfate, 30 min. before surgery	0.2 Gm. 0.2 Gm. 8 mg. 0.5 mg.	5-10 min.	Gradual	Satisfactory sedation preceding and during anesthesia; most patients in this report received spinal anesthesia when surgery was performed

* Used for relief of pain.

† In several instances, the duration of action exceeded 120 minutes.

‡ Used for preoperative sedation.

One of us is at present investigating the angle of tolerance and addiction in dogs, and preliminary work indicates that prostigmine methylsulfate lessens the tolerance and decreases the chances of addiction to morphine.

It is hoped that this report will stimulate other clinical research as regards this problem.

SUMMARY

1. Excellent relief from pain in a variety of cases was obtained by using 1 cc. of a 1:2,000 solution of prostigmine methylsulfate with decreased amounts of morphine.

2. There were no untoward effects in this group of patients using such a combination.

3. Prostigmine methylsulfate relieves the tonic constipation caused by morphine, since it has a marked stimulatory effect on intestinal peristalsis.

4. Further large scale use of this combination in the relief of pain and in the treatment of addiction is indicated.

5. This work further substantiates the cholinergic action of morphine with regard to its effects on pain.

INFLUENZAL MENINGITIS

REPORT OF TWO CASES WITH RECOVERY; ONE CASE COMPLICATED BY PAROXYSMAL TACHYCARDIA

ERNEST L. NOONE, M.D.
DREXEL HILL, PA.

AND
PATRICK J. KENNEDY, M.D.
LANSDOWNE, PA.

In 1933 two cases of influenzal meningitis were presented by one of us (E. L. N.) before the Philadelphia Pediatric Society.¹ One resulted in complete cure; the other showed at autopsy a brain almost entirely devoid of exudate. We believed that death occurred in the second case either because of edema of the brain from serum shock or from pressure changes following cisternal drainage. Both these patients were treated with serum, the first with serum of Dr. Dorothy Wilkes Weiss,² obtained from Parke Davis & Co., the second largely with serum obtained from Dr. Margaret Pittman³ of the Rockefeller Institute.

Two further cases of influenzal meningitis are here presented. We believe that they will be of interest because they were consecutive cases with prompt recovery; further, they presented features of interest, particularly the boy aged 5 years, who had an attack of paroxysmal tachycardia.

REPORT OF CASES

CASE 1.—V. S., a white girl aged 5 years, the daughter of a physician, on the evening of Dec. 29, 1939, felt ill, vomited twice and complained of weird and fantastic dreams. She had a rhinitis. The following afternoon she had projectile vomiting and became semicomatose. Twitchings of the upper extremities were observed; she had a high temperature. Neither her past history or her family history was relevant.

She was admitted to the Mercy Fitzgerald Hospital. She was quite stuporous but moved restlessly in the bed. Muscle twitchings were present in all extremities.

Her eyes were deviated, the pupils equal but dilated and reacting sluggishly to light. The fundi were normal. There was no evidence of intracranial pressure at this time.

The pharynx was definitely injected and hyperemic. The sinuses and mastoids were clear and remained so.

Moderate rigidity of the neck was present. Knee jerks could not be obtained. Kernig's sign was positive and Babinski's sign and ankle clonus were not present.

Her pulse rate was 168 a minute, of poor volume but regular. Her respiratory rate was 44, her temperature 105 F.

The blood count on admission was hemoglobin 9.8 Gm., red blood cells 3,510,000, leukocytes 4,550, neutrophils 80 per cent, lymphocytes 12 per cent and monocytes 8 per cent. A complete list of blood counts is given in table 2.

Blood cultures taken at this time and again on Jan. 13, 1940, were negative.

The first spinal fluid withdrawn was opalescent and contained 3,200 cells per cubic centimeter. Pleomorphic influenza bacilli were present and the culture was positive for *Bacillus influenzae*.

She was immediately given a transfusion of 175 cc. of citrated whole blood followed by intravenous injection of 45 cc. of 5 per cent solution of sodium sulfapyridine. A few minutes later she had a severe convulsion, became cyanotic and had extreme respiratory difficulty. The convulsion stopped after a short time and respiration and color improved.

Owing to lack of space, this article appears here without the tables. They will be included in the authors' reprints.

3. Pittman, Margaret J.: *Exper. Med.* 58: 683-706 (Dec.) 1933.

Sulfapyridine was continued by mouth, averaging 4 Gm. a day. (The patient's weight was 38 pounds [17 Kg.]).

The following day she remained comatose; rigidity of the neck was extreme. The left ear drum became red and paracentesis was performed by Dr. Cornelius McCarthy. Smear and culture of the exudate were negative.

Influenzal serum had been obtained from the Mulford Laboratory of Sharp & Dohme and 50 cc. was given by vein with another blood transfusion of 100 cc.

On the following day, January 11, Fothergill's influenza serum was received from the Massachusetts Department of Health and 8 cc. was administered into the spinal canal. This was accompanied by 5 cc. of human complement, thus following the procedure advised by Ward and Fothergill.⁴ Lack of complement in diseases due to gram-negative organisms was pointed out in 1924 by Kolmer⁵ and again in 1932 by Ward and Wright.⁶

The amount of serum and complement administered by spinal route was limited by the amount of thickened spinal fluid we were able to withdraw.

Thereafter, the Sharp & Dohme serum was administered intravenously and the Fothergill serum as well as some Sharp & Dohme serum by way of the spinal canal.

A survey of treatment and the condition of the spinal fluid is given in table 1. Progress of the case is depicted in figure 1.

Nausea and vomiting occasionally interrupted the oral administration of sulfapyridine, on which occasions rectal administration of the sodium salt was employed.

On the third hospital day, Jan. 1, 1940, spinal fluid cultures were negative but bacilli were still observed in the smear, an experience contrary to our observations in cases prior to the use of sulfapyridine.

The child was still stuporous on January 2 but reacted more hopefully the next day.

January 5, no fluid could be obtained on spinal tap. No pressure was registered on the manometer, and the Queckenstedt test was positive. We do not like to resort to cisternal drainage in these cases unless it is imperative. Later in the day a satisfactory flow of fluid was obtained.

January 6, serum reaction appeared, consisting chiefly of wheals and an elevated temperature, and was a continued feature of the case for several weeks.

Fig. 1 (Case 1).—Progress and treatment chart. Sharp & Dohme serum designated in blocks. Other serum employed is Fothergill's. S. F., spinal fluid.

The mucous membrane of the lips and mouth and particularly of the gums were now covered with a dirty gray exudate. The gums were spongy. A similar finding was described by Moore

and Forbes,⁷ in a case of pneumococcal meningitis and was attributed by them to the sulfapyridine employed.

Dosage of sulfapyridine was decreased and no serum was given for five days.

Bacilli reappeared in smear and on culture January 13. Sulfapyridine administration was increased and serum was

again given. Again culture was negative prior to the disappearance of bacilli from the smear. After January 15 both cultures and smears remained negative. With the exception of moderate serum reactions, the child steadily progressed to a completely normal state.

January 17 sulfathiazole (Squibb) was obtained through Dr. Harrison Flippin and Dr. John Scott, and sulfapyridine was discontinued. Freedom from nausea followed the administration of sulfathiazole.

Later, neurologic examination by Dr. George Wilson showed that the child was completely normal.

CASE 2.—S. H., a white boy aged 5 years, weighing 45 pounds (20 Kg.), recovered more promptly than the first patient and presented the interesting complication of paroxysmal tachycardia.

In earlier years the boy manifested a tendency to hypersensitivity of the mucous membranes and overgrowth of the nasopharyngeal lymphoid tissue. His tonsils and adenoids were removed at the age of 2 years. However, throughout the year of the present infection he had been in excellent health and general physical condition.

March 26, 1940, while sitting on the edge of the bathtub, he fell backward and struck his head heavily in the occipital region on the opposite side of the tub. One may speculate on the influence this accident may have had in opening up pathways of infection and promoting the attack of influenzal meningitis. Certainly there are many cases of meningitis on record immediately preceded by skull fracture.⁸ In this case there was no demonstrable fracture.

The following day he complained of headache. March 28 he returned from school at noon feeling ill, became nauseated and vomited all afternoon. That evening he was irritable and his reflexes were irregular. Kernig's sign was thought to be positive and his pupils were dilated. There was a heavy odor of acetone on his breath.

On the following morning he was admitted to Mercy Fitzgerald Hospital with a provisional diagnosis of head injury. He was intermittently irrational and very restless, his face was flushed and his eyes were rolling. His pupils reacted slowly to light and in accommodation, the left being larger than the right. There was medial strabismus and photophobia. His

8. Prinz, H.: *Chirurg* 5: 544-547 (July 15) 1933.

lips were cherry red. There was no discernible inflammation of the upper respiratory tract or of the ears.

Cervical rigidity was present but intermittent in intensity. He had a bilateral positive Kernig sign. His abdominal reflexes were present, the Babinski sign was not present and the plantar reflex and knee jerks were obtainable.

The temperature was 103 F., the pulse rate 140 and the respiratory rate 32.

X-ray examinations of the skull and cervical vertebrae for fracture or pressure signs were entirely negative.

The white blood cell count was 28,150 cells, 83 per cent neutrophils, 12 per cent lymphocytes and 5 per cent monocytes. Blood chlorides were 476 mg., blood sugar 128 mg., urea nitrogen 10 mg. per hundred cubic centimeters and blood carbon dioxide capacity 32 volumes per cent. A blood culture taken at this time was negative.

On lumbar tap cloudy fluid was obtained under a pressure of 40 mm. of mercury. The cell count was 26,000, polymorphonuclear cells predominating.

The organism observed in the smear was at first thought to be the meningococcus. Accordingly the boy was given 15 cc. of antimeningococcus serum intraspinally and later, when obtained, 20,000 units of Ferry's meningococcus antitoxin in 120 cc. of 5 per cent dextrose solution intravenously. Further amounts of 5 per cent dextrose as well as Hartmann's solution

were of good quality. There was no enlargement of the liver. Cyanosis was present, apparently from the sulfapyridine.

During the night of April 2 an attack of paroxysmal tachycardia began. The rate as registered by the electrocardiograph was 230 a minute. The beats were of good quality early in the day and of poorer quality in the afternoon. The heart was enlarged. The enlargement was confirmed by examination with a portable x-ray apparatus conducted by Dr. J. S. Lehman. There was no suggestion of pericardial effusion. Increased bronchovascular markings in the inner third of the lung fields were compatible with the effect of minimal pressure of active pulmonary hyperemia.

The boy lay quietly in bed as though afraid to move. The vessels of the neck pulsated. There was not much cervical rigidity. The abdomen was flat and there was no enlargement of the liver.

Electrocardiographic studies performed by Dr. Edward Torrance are shown in figures 3, 4 and 5. Tracings were made during the attack, immediately after the attack and eighteen days later. In the opinion of Dr. Torrance, the tracing taken after the attack shows left axis deviation due to dilatation.

Pressure was made over the carotids without effect, but in our opinion the pressure was inefficiently performed and the failure of result inconclusive. The child was given two doses of quinidine, each $1\frac{1}{2}$ grains (0.1 Gm.). The second dose was

Fig. 3 (case 2).—Auricular paroxysmal tachycardia during attack; cardiac rate 230. It was impossible to distinguish P waves because of rapidity of rate. There was no evidence of cardiac damage.

Fig. 4 (case 2).—Tracing taken immediately following attack of auricular paroxysmal tachycardia; cardiac rate 125. Note sharply peaked P waves and left axis deviation, latter probably due to cardiac dilatation during paroxysm.

Fig. 5 (case 2).—Normal tracing except for sinus tachycardia. Left axis deviation disappeared. T waves show improvement.

were given into the vein to effect mineral balance. Sulfanilamide 1.5 Gm. was given by mouth on this date, the 29th.

On the following morning, the 30th, the diagnosis of Pfeiffer's bacillus was determined and treatment started with anti-influenzal serum and sulfapyridine. The dosage is summarized in figure 2 and table 3. An initial dose of sodium sulfapyridine was given, 1.5 Gm. in 5 per cent solution, which was followed by a mild reaction consisting of a brief period of respiratory irregularity and muscular tremors.

At this time the child was acutely ill and delirious, his neck was very rigid and his general posture was that of opisthotonos; his knee jerks were no longer obtainable. He picked continuously at the bed clothes and maintained a disconnected discourse in a drawing voice. He exhibited photophobia, and his left pupil was still larger than the right. The spinal fluid was thick and under high pressure, yet on the evening of that day there was a partial block. Manometer pressure was from 0 to 3 mm. of mercury and only 3 cc. could be withdrawn. By morning there was a free flow of fluid.

Since the child had severe reactions when intraspinal serum was used in this case, the serum was given chiefly by vein. The amounts are presented in figure 2 and table 3.

April 1 urticaria was noted, and this continued for ten days after the last administration of serum. The heart appeared to be somewhat enlarged but the beat was regular and the sounds

were given at 4 p. m. The paroxysmal tachycardia stopped abruptly at 5:20. The pulse immediately became stronger and the rate dropped to 125 a minute and continued to lower. Fluoroscopic study by Dr. Lehman showed a definite reduction in the size of the heart as compared with the previous film study.

The boy was rational that day. Pupillary changes were not recorded during the attack, but on the following day the left pupil was smaller than the right, the reverse of the pupillary changes during the earlier and probably initiative stages of the infection. The pupillary changes, drawing speech and tachycardia may have been influenced by inflammatory changes in the vicinity of the fourth ventricle.

The boy now made a rapid recovery. On April 3 the blood sulfapyridine level was 6 mg. per hundred cubic centimeters. From this point treatment was continued with sulfathiazole, secured through Dr. Harrison Flippin. On April 5 the liver was palpable but was no longer palpable by April 7. On the 6th he had a mild cough and his right ear contained a small amount of exudate. Paracentesis was performed by Dr. McCarthy and, as in the first case, culture was sterile. This may have been part of the serum reaction. On the 6th his knee jerks returned. His further progress was steady and uneventful. The majority of the intraspinal and intravenous treatments were performed by Dr. P. J. Devers.

The immune serum employed was *a* supplied by the Massachusetts Department of Health and *b* supplied by the Mulford Laboratories of Sharpe & Dohme. The latter serum is prepared from six strains of *Haemophilus influenzae* of the Pittman type b (smooth),⁹ secured from patients with mixed virulent respiratory and meningal infections.

COMMENT

As six patients with influenzal meningitis¹⁰ were successfully treated in the Philadelphia district during the winter of 1939-1940, there arises the possibility of the prevalence of a strain less virulent than usual. This does not appear to us to be the case. Certainly these two patients appeared as severely ill in the initial stages as other patients observed in previous years. The good results, in our opinion, can be attributed to the more recent available therapy, particularly sulfapyridine and sulfathiazole.

It is essential to make an early diagnosis. This is sometimes difficult, as is illustrated by case 2, owing to involved onset and the early pleomorphic appearance of the organism. Attention was first drawn to the pleomorphic character of influenza bacilli by Slawyk in 1899 and by many other later writers. Once the diagnosis is made, treatment should be vigorously instituted and continued until all danger of reappearance of the organism in the spinal fluid is past. Herein lies one of the chief advantages of chemotherapy, for sulfapyridine and particularly sulfathiazole can be maintained after reactions have made serum treatment embarrassing and even dangerous. However, we believe that we secured beneficial results in the use of serum alone in earlier cases and that the combined treatment with serum and chemotherapy is to the advantage of the patient.

In connection with the early institution of vigorous therapy may be mentioned the tendency of this infection, untreated, to produce heavy exudate with astonishing pressure about the base of the brain, thus accounting for its further tendency for reappearance of bacilli after apparent initial success.

SUMMARY

1. In two consecutive cases of influenzal meningitis 5 year old children were treated with serum (Fothergill and Mulford) and chemotherapy (sulfapyridine and sulfathiazole); recovery occurred in both.

2. Both cases presented interesting features. In the first case a severe shock and convulsion followed intravenous administration of sodium sulfapyridine. A grayish membrane of the lips, gums and mucous membranes of the mouth also developed, presumably due to the sulfapyridine employed. In the second case the infection was immediately preceded by an injury to the head. This case was complicated by an attack of paroxysmal tachycardia.

In both cases an exudate of the middle ear developed during the infection, the culture being sterile in both instances. Blood cultures in both cases were negative.

3. Both sulfapyridine and sulfathiazole are effective in the treatment of influenzal meningitis. There is less tendency to nausea with sulfathiazole.

SPONTANEOUS REDUCTION OF CERVICAL SPINE DISLOCATIONS

J. T. NICHOLSON, M.D.

PHILADELPHIA

Spontaneous reduction of a dislocation of the cervical spine is the restitution of normal relationship between articular facets by permitting active rotations of the head while it functions as the distraction force.

ANATOMY

The aligned position of the cervical vertebrae is controlled by the opposing articular facets. If there is an abnormal distortion or loss of apposition between the articular facets a dislocation of the cervical vertebra prevails. The articular facets of the cervical spine are sliding joints. These are bound by an articular capsule and are supported by the ligaments of the cervical spine.

In the first cervical vertebra the facets are lateral masses which are joined anteriorly by a narrow arc of bone, the arcus anterior, and posteriorly by a similar but longer arc, the arcus posterior.¹ The lateral masses superiorly rest against the occipital condyles of the skull. Below they articulate with the two superior articular facets of the second cervical vertebra. The odontoid has a flattened cartilaginous surface both anteriorly and posteriorly. Across its posterior surface is stretched the transverse ligament from either lateral mass of the first cervical vertebra. From its tip run two alar ligaments and an apical ligament joining the basilar process of the skull. These ligaments are covered with the tectoria membrane, which extends from the basilar process of the occipital bone over the posterior surfaces of the vertebral bodies. The tectoria membrane in turn is covered by the posterior longitudinal ligament, which is also attached to the basilar process of the skull and the posterior surface of the vertebral bodies. Anteriorly the first cervical vertebra is supported by the anterior longitudinal ligament, which extends from the inferior surface of the basilar process of the occiput attaching along the anterior surface of the vertebral bodies. Joining the arcus posterior to the posterior margin of the foramen magnum is the atlanto-occipital membrane. The lower margin of the arcus posterior is joined to the second cervical lamina, and this lamina in turn to the third and it and the successive laminae by ligamenta flava. The inferior facets of the second vertebra are relatively further posterior than the superior and are transitional toward a lateral plane with the articular surface obliquely anterior and caudad. In turn the corresponding superior facets of the third cervical vertebra have a position with the articular surface obliquely posterior and cephalad. Successive articulations of the lower vertebrae in the cervical region are more in the lateral plane but otherwise are similar to those between the second and the third. Interposed between the vertebral bodies excepting the first and second is a fibrocartilage disk. This is covered anteriorly by the continuation of the anterior longitudinal ligaments and posteriorly by the posterior longitudinal ligament.

From the Orthopaedic Clinic of the Children's Hospital.

Read before the Section on Orthopedic Surgery at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

9. Pittman, Margaret: *J. Exper. Med.* 53: 471-492 (April) 1931.

10. Personal communication: Arnat, John, M.D., Episcopal Hospital, one case; Chapple, Charles, M.D., Chestnut Hill Hospital, one case; Harvie, Frederick, M.D., Service of Dr. Joseph Stokes, University Hospital, one case; Wilder, Theodore, M.D., Abington Hospital, one case. Dr. Harvie's case is particularly interesting because the child was only 21 months old. Dr. Chapple's patient was 2½ years of age. Both these children were treated with sulfathiazole.

CLASSIFICATION

The dislocation is common in the upper two cervicals. This may be due to the leverage of the head and the horizontal position of the facets. The dislocation is described as anterior, right or left rotary, posterior

Fig. 1 (case 2).—Side view of the typical position of the head with a right unilateral rotary dislocation of the first cervical vertebra.

and right and left lateral. A fracture of the odontoid or the accessory processes generally accompanies the latter two types. Both articular facets are displaced in all but the rotatory dislocations.

ETIOLOGY

Cervical dislocations may result from trauma, infection, paralysis or congenital defect. Traumatic dislocations are frequently associated with a fractured odontoid or an accessory process. Automobile accidents, falls on stairs, falls from bed, sudden turns of the head, and postoperative overcorrection of torticollis are some of the associated accidents.

Following infection, either in the vertebral bodies or in adjacent cervical tissues, the dislocation is occasionally spontaneous.² The ligaments supporting the cervical vertebrae become relaxed as a result of bone destruction, joint distention or bone decalcification. The vertebrae are destroyed by pyogenic, tuberculous or syphilitic osteomyelitis. The distention of the joints may be from the hyperemia induced by the adjacent infection or from direct extension of infection, such as sinusitis, pharyngitis, tonsillitis, mastoiditis, adenitis and dental abscesses through the neighboring cervical tissues. Decalcification of bone has been reported in the presence of hyperemia resulting from an associated infection.³

Paralytic dislocations from muscle imbalance have occurred in the subacute stage of poliomyelitis.⁴

Congenital absence of the odontoid⁵ and anomalies in the cervical facets are responsible for some cervical dislocations.

DIAGNOSIS

There are definite clinical manifestations which have been described by several authors that lead one to suspect a cervical dislocation. The head is held in a torticollis position. In unilateral dislocations the head is tilted to the side of the dislocation and the chin rotated away from it. The head can be flexed only a few degrees to the opposite side and the chin cannot be rotated as far to the dislocated side. The head is in flexion and extension accentuates pain. The patient frequently supports his head with his hands when rising from a prone position. The entire body is turned when the subject attempts to see over the opposite shoulder. Pain is referred to the occiput and mastoid in dislocations of the upper cervicals. These areas are sometimes tender to touch. The mouth may be difficult to open because of the flexed position of the head. If the pharynx can be seen it will be noticed to bulge to the side opposite the dislocation, if it is unilateral. The paraspinal muscles are prominent posteriorly on the side opposite the dislocation. Occasionally a sensation of grating is experienced with attempted rotation of the head. Dysphagia and voice change seldom occur.

Fig. 2 (case 2).—Front view of the typical position of the head with a right unilateral rotary dislocation of the first cervical vertebra.

Paralysis is rare in the subject who survives the initial dislocation force. If there is paralysis, it is evidenced mainly in the arms.

The x-ray film verifies the diagnosis (figs. 1, 2, 3 and 4). In dislocations of the first cervical vertebra the

5. Roberts, S. M.: Congenital Absence of the Odontoid Process Resulting in Dislocation of the Atlas, *J. Bone & Joint Surg.* 12:923 (Oct.) 1933.

lateral view reveals a lordosis of the cervical spine with the anterior arch of the first cervical extending anterior to the odontoid, unless the odontoid is fractured. In the other cervical dislocations the body of the dislocated vertebra projects beyond the anterior border of the vertebra. The posterior arch of the dislocated vertebra appears broader because it is tilted. The posterior borders of the vertebral bodies do not form a continuous arc but angle at the site of the dislocation.

The anteroposterior view discloses the spine of the dislocated vertebra pointing to the opposite side from which the chin is rotated. The spinous processes of successive vertebrae gradually appear toward the midline.⁶ Visible between the first and second vertebrae is the greater width of one articular space. In the other cervical vertebrae there is an increased distance between the transverse processes on the one side and a decreased distance on the opposite side. In a forward displacement of the first cervical both articular spaces are decreased. In forward displacement of the other vertebrae there is a diminished distance between the transverse processes, and the intervertebral space is narrowed or obliterated. In lateral displacements the odontoid appears nearer one lateral mass than the other, and in the succeeding vertebra the transverse process and vertebral body project farther to one side.

METHOD OF REDUCTION

The spontaneous method is developed from Stookey's⁶ treatment of injuries of the cervical spine in which hyperextension of the neck was obtained by compressing the upper edge of an air mattress with adhesive tape. The technic varies in spontaneous reduction in that the subject is placed recumbent with his shoulders at the upper margin of three short mattresses tiered on a fracture bed (fig. 5). The head is not supported; its weight distracts the joints of the cervical spine and holds the neck in hyperextension. No apparatus, such as a Sayre collar or skeletal traction tongues, is used. The head of the bed is elevated on shock blocks to prevent the subject from sliding. Buck's extension is employed on both legs of small children in addition to elevating the head of the bed. The position at first may be uncomfortable from strain on the anterior musculature of the neck, in which case the subject is shifted toward the foot of the bed so that the neck rests over the end of the mattress, thus receiving some support. Gradually in the following twenty-four to forty-eight hours the subject is positioned toward the upper end of the bed until the neck is beyond the mattress and the head is hanging free.

After an additional twenty-four to seventy-two hours with the head hanging free, the dislocation is found to be reduced. This is determined by the ability to rotate passively and flex laterally the cervical spine an equal distance to either side.

X-ray examination is facilitated by lifting the mattress with the subject onto a stretcher. This does not disturb the position of the head. The films are taken in the anteroposterior and lateral position without moving the head by holding the cassette on the side or in back of the neck.

Reduction is maintained by a plaster bandage from head to pelvis. It is necessary to have the chin and

forehead included to prevent flexion of the head, which would cause redislocation. The cast is extended to the pelvis to guard the spine against flexion and to distribute its weight on the iliac crests. The method of applying the plaster cast is an adaptation of that advocated by Brookes⁷ in 1933: The subject is transferred from the mattress without supporting the head to the canvas sling of an Abbott frame so that the back rests on the sling and the head hangs dependent over the end. In this position the body jacket is applied. When this dries sufficiently to withstand pressure, a table of equal height as the sling is pushed beneath the subject. The sling is released, which permits the table to support the subject's trunk. The frame and sling of canvas are removed. A 4 inch muslin bandage with a longitudinal

slit in its midportion, permitting it to be slipped over the patient's head, to run beneath the chin and occiput, is arranged so that the ends may be tied behind the operator's back.⁷ In this way the operator can exert traction and control the amount of extension of the neck. The extension that occurs at the occipital-axial joint is not necessary and not desirable, as it will fix the subject's head looking heavenward and make feeding and balance difficult. The head cast is then applied over the traction bandage, which can be withdrawn after the head and body parts of the plaster cast are joined. The subject is allowed to sit up the day after the application of the plaster cast. He is permitted to walk the third day and is discharged as soon as he can navigate without difficulty.

The dislocations are held from twelve to sixteen weeks in plaster and eight additional weeks in a Thomas collar. The Thomas collar is necessary to permit rehabilitation of the cervical muscles. These muscles have undergone marked atrophy. In this condition they fatigue readily. Strain is then thrown on the ligamentous structures of the cervical spine. This strain

CASE 7.—D. P., a boy aged 5 years, fell from bed Aug. 4, 1938. The complaint was pain on the left side of the neck and inability to move the head. X-ray examination revealed a dislocation of the second cervical vertebra. After one week the dislocation failed to reduce with dependent head traction. (Great difficulty was encountered in keeping the patient in a satisfactory position. A discharging ear also developed.) Manipulation of the neck by Taylor traction and Walton maneuver was unsuccessful. A body jacket was applied and worn for three months. Six months after the cast was removed there was no change in the position of the vertebra. The subject subsequently moved to California.

CASE 8.—J. B., a boy aged $7\frac{1}{2}$ years, had a series of infections of the upper respiratory tract during the winter and had just finished convalescing from an acute pharyngitis. On March 14, 1939, he was permitted to return to school and was riding in the rear seat of a sedan when it was struck by another car. The child was thrown to the floor of the sedan and sustained a bump on the head. Examination at a local hospital was negative for injury. The child played with other children that afternoon. The following morning he awakened with a stiff neck. The head was tilted to the right and the chin rotated to the left. There was pain on attempted motion of the neck. Physical examination was negative except for pain and the characteristic position of the head. The x-ray appearance was

Fig. 7 (case 6).—(a) A fracture through the base of the odontoid with anterior dislocation of the first cervical reduced spontaneously and (b) united after three months of immobilization in plaster.

interpreted as a rotary displacement of the right inferior facet of the second cervical vertebra on the third. The child was hospitalized and after forty-eight hours of dependent head traction the dislocation was clinically and roentgenologically reduced. A plaster cast was applied and worn until May 12. A Thomas collar was worn for an additional month. On March 15, 1940, x-ray examination showed a normal position of the vertebrae and clinical examination was negative.

CASE 9.—M. P., aged 4 years, a feeble-minded boy, fell from his crib eight days after a cleft palate operation. A dislocation of the inferior right facet of the second cervical vertebra was diagnosed by x-ray examination, Dec. 23, 1939. This dislocation failed to reduce spontaneously. An infection of the upper respiratory tract and sinusitis developed. The dislocation could not be reduced by manipulation. An open operation was done March 26, 1940, but reduction could not be obtained. Further deformity was averted by wiring the second and third cervical laminae together. June 5 the position had been maintained two weeks after plaster fixation had been removed.

CASE 10.—J. D., a man aged 60, had delirium tremens, fell down stairs May 30, 1935, sustained a fracture of the odontoid with anterior displacement of the first cervical vertebra and a fracture of the right humerus. He was admitted the same day to the Philadelphia General Hospital. There was no neurologic involvement. It was necessary to feed him through a

nasal tube because of impending delirium tremens. After four days a decubitus ulcer developed on his chin from the Sayre collar traction. Dependent weight of the head was then tried. In twenty-four hours reduction had been spontaneously accomplished. A cast was applied from the head to the pelvis. He tore this cast off twenty-four hours later and was then transferred to the psychiatric ward. The dislocation recurred but no symptoms indicative of cord pressure developed up to the time of his death from pneumonia six weeks after admission.

CASE 11.—J. W., a man aged 25, on Aug. 10, 1937, dove into the breakers at the beach. He was helped from the water. His hands pained and lost their grip and he could not elevate his arms. His legs gave him no support. He was admitted to a local hospital and Sayre traction was applied. An ulcer developed on his chin after seven days.

On September 4 he was transferred to the Philadelphia Orthopaedic Hospital. He had no power in the left hand and marked weakness of the right hand, shoulders and upper arms but no sensory disturbance. The lower extremities were normal except for hyperactive reflexes.

X-ray examination revealed a forward position of the fifth cervical vertebra on the sixth with a compression fracture of the latter.

Since muscle power had steadily improved, the head was placed in a dependent position September 11. X-ray examination revealed excellent alignment five days later. There was, however, extensive edema of the scalp. A jacket was applied September 16 and the subject was ambulatory September 19. A few days later it was necessary to change the cast, as it had become loosened about the head when the edema subsided.

The reduction of the vertebral fracture was not obtained in this case, as the position of hyperextension was not maintained. The patient regained complete power in his arms, had no symptoms referable to his neck, and returned to work in four months as an electrician.

SUMMARY

A spontaneous method of reducing dislocation of the cervical spine proved applicable and successful when other methods could not be applied or had to be discontinued because of lack of the patient's cooperation. Presence of infection or appearance of a decubitus ulcer on the chin. This method of reducing uncomplicated dislocation of the cervical spine was tried on nine children and two adults. The method was uniformly successful in the reduction of spontaneous dislocation. It failed in two traumatic dislocations of the second cervical vertebra. The dependent head theoretically was not applicable in all cases immediately after a traumatic injury. It should not be used in posterior dislocations. Edema of the scalp was a complication arising from the dependent position of the head of one adult. In the two failures there was a danger of spreading a respiratory infection through the sinuses or the middle ear. The reduction was determined clinically by symmetrical rotation and lateral flexion on passive motion of the head. X-ray examination was made without disturbance to the position of the head.

1614 Locust Street.

ABSTRACT OF DISCUSSION

DR. W. H. VON LACKUM, New York: Dr. Nicholson has presented an interesting review of cases of the spontaneous and traumatic dislocations of lesser degree, treated by a method not previously described. In recent years much interest has been shown in lesions of the cervical spine which present this clinical picture of a painful neck, tilted to one side and rotated to the opposite side and associated with muscle spasm. They are the lesions of the atlanto-epistropheal and of the lower cervical spine, associated with trauma exudation or inflammation and an occasional case of paralysis and congenital anomaly in or about the atlanto-epistropheal and lower joints of the

cervical spine. In the atlanto-epistropheal region they are, according to Coutts, rotation deformities, distention-subluxations, dislocations and fracture dislocations. That a fine line of distinction between the rotation deformities, subluxations and slight dislocations has not been made until recently is evidenced by the lack of uniformity in the various older descriptions of the pathology. However, in the exudative reactions in and about the atlanto-epistropheal joints there does exist this unstabilizing pathologic process in joints otherwise stable, which is an entity in itself and one that is as well recognized as the traumatic dislocations and fractures encountered in the lower cervical region. The unstable nature of these joints under conditions of mild stresses and trauma indicated by their capacity to subluxate and dislocate further typifies the mechanical setup in the spinal mechanism where ranges of mobility are great. In my experience at the New York Orthopedic and other hospitals I have found that in gentle head halter traction, at times assisted by manipulation, later supported by head helmet body jackets and removable collars, we have a fairly dependable and satisfactory form of treatment. This of course admits the tendency of these lesions to recur and the occasional failures that necessitate surgical fixation. Dr. Nicholson is offering an additional form of therapy which, if we choose, we may use safely in these cases and apparently a form of treatment that will succeed in some of the cases in which the other more recognized forms of treatment fail. While his series is small, his high percentage of successful reductions and their subsequent stability, as shown by adequate follow-up, speaks well for the method. He has noted some contraindications. Positive indications would seem to hinge around cases with lesions associated with chin decubitus, with mandible injury, painful cervical adenitis and parotitis, as well as among those cases that fail with traction and manipulation.

DR. BARBARA B. STIMSON, New York: Dr. Nicholson's paper has been most enjoyable. He has not been fair, however, to his own ingenuity to call his method a "spontaneous" reduction! Actually, the method is that of traction with the weight of the head exerting the pulling force on the cervical vertebrae by virtue of the described position. The spontaneity has been considerably assisted by the doctor. The series of cases has interested me greatly. I have not had the opportunity to study so many of the complete dislocations, and those I have seen, six in all, were all of traumatic origin. Of these two without fracture were reduced by manipulation. The others were all associated with fracture. One was reduced by traction on an air mattress, as described by Dr. Stookey, one by direct head traction, one was operated on and one refused operation, though reduction could not be maintained. He subsequently went on to spontaneous fusion in a partially corrected position. Over 250 cases of incomplete dislocation have been treated by head traction in the majority of instances. There are two questions I should like to ask. Dr. Nicholson says that his method is not applicable to early traumatic cases. How does he treat them? I feel strongly that the earliest possible reduction of dislocations and fractures is not only easiest but also does least damage to the adjacent soft parts. Surely he would not keep his patient on ice, as it were, until he felt it was safe to apply his method. I have been much troubled by nausea and vomiting in patients treated by traction, either by the Stookey method or by direct head pull. I would think that the extreme position described by Dr. Nicholson would tend to increase this discomfort, and I would like to ask him if this is so.

DR. JESSE T. NICHOLSON, Philadelphia: Dr. Stimson's inquiry as to why measures are not taken to reduce the dislocation at once should be qualified. It is not customary in Philadelphia any more than in New York to neglect the early treatment of the subjects. The delay is suggested before placing the head dependent, as this position might add to the local cord edema in the acute case. It therefore should not be tried until this complication is minimized. But two adults are included in the series. Both have developed pressure sores on the chin following several days traction with a Sayre collar.

Nausea was a minor complaint in one adult. This subject, however, developed extensive edema of the scalp after the head hung three days. When the patient became ambulatory in a plaster cast, the edema subsided so that in four days it was necessary to apply another cast for adequate fixation of the head.

Clinical Notes, Suggestions and New Instruments

SULFATHIAZOLE URINARY CALCULI IN THE KIDNEYS, URETERS AND BLADDER

IN THE ABSENCE OF MARKED URINARY CHANGES FOLLOWING SULFATHIAZOLE THERAPY

SAMUEL A. LOEWENBERG, M.D., NORMAN G. SLOANE, M.D.,
AND PAUL CHODOFF, M.D., PHILADELPHIA

Sulfathiazole (2 sulfanilamide-thiazole) is the newest of the group of chemotherapeutic agents employed in the treatment of pneumococcal pneumonia. Its efficacy in pneumonia is being thoroughly investigated in many of the larger hospitals in this country. Clinical reports¹ and our own results show that in its therapeutic effects sulfathiazole in pneumonia compares favorably with sulfapyridine and that it is preferable to sulfanilamide. It also has the added advantage of being less toxic and less likely to cause some of the complications encountered after the use of either of these other drugs. Since sulfathiazole is still on trial it is important to record any of the complications or sequelae that may arise from its use. Reinhold, Flippin and Schwartz² observed that sulfathiazole is not as readily reabsorbed from the kidney tubules as are sulfapyridine and sulfanilamide. Gross, Cooper and Scott³ reported the formation of sulfathiazole crystals in the distal collecting tubules of rats' kidneys after the administration of sulfathiazole. Pepper and Horack⁴ reported the first instance of crystalline sulfathiazole concretions in the renal tubules of a patient treated for pneumonia with sulfathiazole. Our case is, to our knowledge, the second proved case of sulfathiazole renal concretions and the first in which there were no clinical signs of kidney inefficiency. Added interest in the case was the development of acute vegetative endocarditis and hepatic and splenic necrosis, which may be explained on the basis of the pneumococcemia and is not attributed to any toxic effect of the drug.

REPORT OF CASE

History.—H. S., a woman aged 49, was admitted to our service at the Philadelphia General Hospital March 29, 1940, with signs of left basal pneumonia.

She became ill March 17 with what was considered a cold or grip; her symptoms became progressively worse and she was sent to the hospital twelve days after the onset of her illness. On admission she complained of chills, pain in the chest, dyspnea, cough and hoarseness; there was blood-streaked expectoration.

Examination.—The patient was stout; she was thoroughly conscious and alert. The temperature was 102 F., the pulse rate 120 per minute and the respiratory rate 30 per minute. Her face was flushed; she had herpes labialis; the veins in her neck were distended and she was dyspneic.

The heart was enlarged and fibrillating, the heart rate being 160 per minute, and there was a suspicion of a murmur at

URINARY CALCULI—LOEWENBERG ET AL.

JOUR. A. M. A.
DEC. 14, 1933

the mitral area which could not be timed because of the fibrillations. The blood pressure was 120 systolic, 80 diastolic.

The lungs showed evidence of lobar consolidation at the left base.

The abdomen was distended; the liver extended 11 cm. below the right costal margin; it was soft and its edge was rounded; the spleen was readily palpable. There was no ascites or superficial edema.

Sputum typed immediately after admission showed pneumococcus type XXV. The blood culture was positive within twenty-four hours for pneumococcus type XXV. Analysis of the blood showed hemoglobin content 68 per cent, erythrocytes 3,100,000, leukocytes 19,200, polymorphonuclears 80 per cent, lymphocytes 18 per cent, monocytes 2 per cent. The Wassermann and Kahn reactions of the blood were plus 4.

The first specimen of urine gave an acid reaction; specific gravity was 1.020; tests for albumin and sugar were negative; there were no casts; an occasional leukocyte was present.

Course in the Hospital.—Soon after admission, in addition to digitalis, she was given 3 Gm. each of sulfathiazole and sodium citrate, which dose was repeated in four hours; subsequently she received 1 Gm. each of sulfathiazole and sodium citrate every four hours until 25 Gm. had been given. April 1, the end of the fourth day, her temperature reached normal by lysis and she showed general improvement; at this time the administration of sulfathiazole was discontinued.

April 3 she had a relapse; the temperature rose to 103 F., the respiratory rate to 45 and the pulse rate to 120. She was extremely hoarse; the heart rate was regular and there was a loud systolic murmur audible over the entire precordium. The blood pressure was 130 systolic, 50 diastolic. The lungs showed an extension of the consolidation to a somewhat higher level on the same side. A profuse diarrhea developed and she became jaundiced. A second blood culture was positive for pneumococcus type XXV. Sulfathiazole and sodium citrate 1 Gm. each was ordered to be given every four hours, and she was placed in an oxygen tent. Her mind was clear.

April 6 she felt better; the temperature was 100 F. T. Lungs showed signs of resolution. The heart showed good compensation; the pulse rate was 100; there was a loud harsh systolic murmur over the body of the heart.

April 7 the temperature was 105.4 F., the pulse rate 152 and the respiratory rate 60. Her mentality was clear. There was

Fig. 2.—Microscopic appearance of crystals of acetylsulfathiazole taken from the concretions.

Fig. 1.—Frozen section of kidney showing acetylsulfathiazole concretions (A) and collecting tubules (B).

April 5, because of the pneumococcemia and endocarditis, a tentative diagnosis of acute bacterial endocarditis was suggested and the administration of 100,000 units of type XXV pneumococcus serum was attempted. Though she had not shown any serum sensitivity to the usual tests, a severe chill developed and the temperature rose to 105.4 F. (axillary) after only half of the 100,000 units had entered her vein. Further administration had to be discontinued.

tubular breathing near the angle of the right scapula; the liver and spleen were very large; the patient, notwithstanding the dyspnea, seemed fairly comfortable.

April 8 there was no change in her general appearance or in her clinical manifestations. The heart rate was rapid and regular; sounds were muffled and the murmur was not audible. At 3 p. m. she suddenly died.

During the patient's entire stay in the hospital (ten days she received, in addition to symptomatic treatment, 52 Gm. of sulfathiazole. Though the temperature reached normal on the fourth day, she had a relapse and remained acutely ill, distressingly dyspneic and quite cyanotic; these symptoms were not relieved in the oxygen tent or by other measures. The heart rate slowed and the rhythm became more regular under the influence of digitalis, but a loud systolic murmur developed over the body of the heart which was audible with equal intensity over the entire precordium. The blood pressure remained fairly constant between 126 systolic, 70 diastolic, to 130 systolic, 60 diastolic, and the day she died it was 130 systolic, 50 diastolic. She was mentally alert until the last. At no time did she complain of urinary symptoms. Twenty-four hours before death the temperature rose to 105.4 F.; the heart murmurs disappeared and there was evidence of cardiac dilatation. Death was sudden.

The blood counts made during her stay in the hospital are given in table 1.

The blood Wassermann and Kahn tests gave a plus 4 reaction. Blood urea was 19 mg. per hundred cubic centimeters on admission and 20 mg. several days later. Blood cholesterol was 118 mg. with 10 per cent esters. Blood sulfathiazole levels were from 5 to 7.6 mg. per hundred cubic centimeters. Results of urinalyses are given in table 2.

Culture of the urine on April 3 gave negative results. The fluid intake and output were within normal proportion. Culture of the feces on two occasions showed an unusual predominance of *Staphylococcus aureus*.

Autopsy was done by Dr. H. G. Schlumberger.

External Examination.—The body showed no cyanosis or edema. The skin had a slightly icteric tint but otherwise no abnormal pigmentation was noted.

Internal Examination.—Both pleural spaces were almost obliterated by dense fibrous bands; no free fluid was present. The peritoneal surfaces were smooth and glistening; the mesentery and omentum contained a great deal of fat. No free fluid was present in the peritoneal cavity, and the normal visceral relationships were preserved.

Pericardium: The surfaces were thin, smooth and glistening except for a 5 by 3 cm. area of opacity in the visceral layer covering the anterior part of the right ventricle. The usual amount of clear, pale yellow fluid was contained within the pericardial sac.

Aorta: The intima showed only a few small atheromatous plaques in the abdominal segment. The wall of the ascending aorta was moderately thickened and several white, waxlike plaques were seen on the intimal surface.

Heart: The myocardium was very flabby and uniformly soft and reddish brown. Both ventricles were slightly dilated; the auricles were filled with cruor. On the tricuspid leaflets, near the free margin there was a 1 by 1 cm. firm, friable, yellow mass closely adherent to the underlying valvular endocardium. The pulmonary valve showed no abnormalities. The mitral valve was thin, smooth, flexible and of average length, and there was nothing suggestive of vegetations. The papillary muscles were of average size; the chordae tendineae were not shortened or fused together. On the anterior cusp of the aortic valve there was a yellowish green, homogeneous, friable mass measuring 1.5 by 1 by 1 cm., which was firmly adherent to the ventricular surface of the valve. The remaining two cusps showed several firm white nodules measuring approximately 1 by 1 mm., arranged along the line of closure. The coronary vessels were free from any significant atherosclerosis.

Lungs: The consistency of both lungs was somewhat increased throughout but the left lower lobe was distinctly consolidated. The cut surfaces of the right lung and left upper lobe were hemorrhagic, and a great deal of blood tinged fluid escaped when pressure was made on the lung parenchyma. The left lower lobe on section was somewhat dry and more granular than the cut surfaces of the other lobes. The bronchial mucosa was hyperemic and edematous. The pulmonary vessels contained no thrombi. There was no evidence of suppuration in any portion of either lung. The regional lymph nodes were not remarkable.

Spleen: The spleen was greatly enlarged and so soft that on sectioning the pulp was almost semifluid. The capsule was thin, smooth and slate gray; the pulp was uniformly purplish red. The follicles and trabeculae could not be distinguished.

Kidneys: Both organs were moderately enlarged, of average firmness and cut with normal resistance. The capsules stripped

Genitalia: The uterus measured 5 by 6 by 3 cm.; it cut with the usual resistance. The endometrium averaged 2 mm. in thickness and was uniformly dark red. The fallopian tubes were tortuous, bound down by fibrous adhesions and in several places were moderately dilated. The ovaries were small, firm, white and fibrous.

Gastrointestinal Tract: The peritoneal surfaces were smooth and pale gray. The stomach contained a small amount of gray opaque fluid. The mucosa was smooth and pallid and showed numerous petechiae. The lumen of the large and small intestine was of average size and the contents were not abnormal. The mucosa was intact throughout and essentially normal in appearance. The mesenteric blood vessels showed no change.

TABLE 2.—*Urinalyses*

Date	Specific Gravity	Reaction	Albumin	Sugar	Microscopic Observations
3/31/40	1.020	Acid	Negative	Negative	Occasional leukocytes
4/ 5/40	1.016	Alkaline	Negative	Negative	Occasional leukocytes; occasional epithelial cells

Liver: This organ was enlarged, moderately soft and uniformly yellow. Resistance to cutting was somewhat decreased and the cut surface was uniformly pale yellow and soft with indistinct markings.

Gallbladder and Ducts: The gallbladder was slightly distended by 25 cc. of light amber colored bile which flowed readily through the ducts and from the ampulla of Vater. The wall was moderately thickened, and attached to the mucosa were numerous orange granules which in some places formed definite ridges. The bile ducts were not dilated and contained no calculi.

Pancreas: This organ was of average size, shape and consistency. It was a yellowish brown, firm and distinctly lobulated. The surrounding fat was of average amount and of the usual color. The pancreatic ducts appeared normal.

Adrenals: Both adrenals were of average size, shape and consistency. The medullary portions were a gray brown and firm. The cortical layers were dark brown instead of the usual deep yellow.

Vertebrae: The cancellous portion of the bodies contained uniformly pale red marrow.

Chemical Examination of the Concretions.—The kidney calculi on chemical examination were found to consist of acetyl-sulfathiazole to the extent of about 50 per cent of the dry weight. A slight trace of free sulfathiazole was present.⁵

SUMMARY AND COMMENT

Sulfathiazole concretions were found in the kidneys, ureters and bladder of a patient treated for pneumonia with sulfathiazole who did not present any evidence of disturbance of the urinary tract. It is therefore of clinical importance to study the effects of sulfathiazole on the kidneys so as to determine whether sulfathiazole crystals are nonirritating to the kidneys or whether there is a latent period between the formation of crystals in the urinary tract and the development of kidney insufficiency. If sulfathiazole crystals can remain in the kidneys, ureter and bladder without causing early clinical signs of renal damage, it will be desirable to determine its ultimate effect on the kidneys by studying the renal functions of patients, who were treated with the drug, for a period of one year after the drug has been discontinued.

Sulfathiazole in this case had no effect on the pneumococcemia or on the acute bacterial endocarditis.

How frequently crystallization of sulfathiazole may occur in the urinary tract is as yet unknown. Of sixteen autopsies reported by Flippin⁶ on patients treated with sulfathiazole, none showed uroliths, though among the hundred or more patients treated with that drug there were quite a few who had mild urinary disturbances.

1905 Spruce Street.

4/ 8/40	52	2,600,000	13,000	74	58	16	10	10

with ease, revealing a smooth pale red surface. On section the cortex was found to be from 1 to 1.5 cm. in width, of a uniform pale red and indistinctly demarcated from the medulla. In the calices and pelvis there were numerous bright orange colored irregular shaped calculi measuring from 1 to 2.5 mm. in diameter. The pelvis were not dilated and the mucosa was uniformly smooth and moderately hyperemic.

Urinary Tract: The serosal surfaces were smooth and pale pink. The ureters were slightly dilated and contained numerous granules similar to those found in the calices. The left ureter near its source was almost completely occluded by a mass of the same type of orange colored calculi. The bladder was small and contracted; the mucosa was slightly hyperemic, and attached to its surface were several granular masses similar to those noted in the ureters and pelvis.

CONGENITAL HYPERTROPHY OF THE VERUMONTANUM

FREDERICK PILCHER JR., M.D., AND HAROLD W. PRICE, M.D.
CALGARY, ALTA.

Congenital hypertrophy of the verumontanum is one of the rarest lesions in the posterior urethra. A case in which this anomaly was discovered at autopsy led us to a thorough review of the literature, which disclosed only thirteen previously reported cases. In the case recorded here the lesion was somewhat different from any of those observed.

REPORT OF CASE

A. P. D., a white boy, was born at the Calgary General Hospital on July 2, 1937. This was the mother's second pregnancy. A previous and a subsequent child are both normal and well. Pregnancy and delivery were normal. The birth weight was 8 pounds 10½ ounces (3,926 Gm.). Routine physical examination after birth disclosed nothing abnormal. After the usual postnatal drop in weight the child began to gain normally. On the sixth day there were fever and diarrhea, but these lasted

Fig. 1.—Entire urinary tract showing the dilated kidneys, tremendous dilatation of the ureter and thickened hypertrophy of the bladder.

only two days. Thereafter his progress was normal and uneventful. The child and mother left the hospital on the fourteenth day and went home to the country.

On July 22 the child was brought back to the city by his mother. He had nursed poorly, had not taken his bottle well and on the day of examination had refused to take anything by mouth. The child was markedly emaciated and moribund. The abdomen was soft and scaphoid, and peristaltic waves were visible. Both kidneys were easily palpable and larger than normal. Otherwise examination was negative. The child was sent to the hospital, where subcutaneous fluids were administered. He died five hours after admission.

Autopsy performed by Dr. Lola McLatchie showed marked emaciation and pale dry tissues. Complete examination was otherwise essentially negative except for the urinary tract. The illustrations show clearly the appearance of the fixed specimen. Both kidneys were full of thick purulent urine. The

From the Calgary Associate Clinic.

markedly enlarged and elongated verumontanum projected into the bladder. Lifted forward, the verumontanum acted as a valve which completely or almost completely occluded the urethra. There was no other obstruction in any part of the urethra.

LITERATURE

The three congenital obstructive lesions observed in the posterior urethra are valves, contractures and hypertrophy of the verumontanum. According to the literature, valves are the

Fig. 2.—A clearer view of the elongated hypertrophied verumontanum.

most common and hypertrophy of the verumontanum the least common. Young, Frontz and Baldwin¹ in 1919 presented the first thorough review of congenital valves in the posterior urethra. Since then, painstaking reviews of the literature and reports of personal cases have been published by numerous authors. In none of these papers, however, is hypertrophy of the verumontanum mentioned as the sole cause of obstruction. In the presence of valves there often is observed a variable

Fig. 3.—Section through the elongated verumontanum and region of the bladder neck; reduced from a photomicrograph with a magnification of 9 diameters.

degree of enlargement or distortion of the verumontanum, but the valves act as the obstructing agent. Enlargement of the verumontanum alone as the cause of obstruction was first

1. Young, H. H.; Frontz, W. A., and Baldwin, J. C.: Congenital Obstruction of the Posterior Urethra, *J. Urol.* 3: 289-354 (Oct.) 1919.

reported by Bugbee and Wollstein² in 1923. They observed seven cases at autopsy and one clinical case. All but two of the patients were under 1 year of age and the oldest was 3½ years. Robinson³ in 1927 reported an autopsy specimen from a man aged 19. Dodson and Lorraine⁴ observed during life a youth aged 19 in whom hypertrophy of the verumontanum was a cause of urinary obstruction and retention, and a good result followed fulguration of the verumontanum. Baldrige⁵ reported another case in which cure followed fulguration of the verumontanum in an 11 year old patient. Somerford⁶ in 1936 again observed this lesion at autopsy in a child aged 11 years. The latest report is that of Grant⁷ in 1938 in which he mentions a boy aged 13 years in whom hypertrophy of the verumontanum was noted during life and relief of obstruction followed fulguration of the verumontanum.

COMMENT

There is no satisfactory explanation for congenital hypertrophy of the verumontanum. The greatly enlarged verumontanum probably acts as a ball valve just in front of the external sphincter in the same way that median lobe prostatic hypertrophy acts in the region of the internal sphincter. Mechanical obstruction to the flow of urine is produced.

The pathologic changes in the urinary tract and the symptoms are similar to those resulting from enlargement of the prostate gland or any other type of infravesical obstruction. There is dilatation of the posterior urethra behind the verumontanum. During the earlier stages of obstruction there are hypertrophy of the bladder with trabeculation, hypertrophy of the trigon, perhaps diverticulum formation and inflammation, dependent on the degree of associated infection. Later, when decompensation of the bladder occurs, there follows dilatation of the bladder, which together with inflammatory changes in the bladder wall result in incompetence of the ureterovesical valve mechanism. Ureteral and pelvic dilatation occur, and in the most advanced cases the renal parenchyma becomes a thin shell. This compression atrophy, accompanied in many cases by infection, eventually reduces renal function to a point at which it will no longer support life.

The early symptoms are those of urinary obstruction. Later there are renal insufficiency and uremia. Frequency of urination is the most common symptom. With associated infection, frequency often becomes very marked with almost constant dribbling. Enuresis may be the most prominent symptom. One may observe in older children considerable straining, hesitancy and difficulty in voiding. When bladder distention occurs it may be observed as a mass in the lower part of the abdomen. Recurrent episodes of fever, often diagnosed as pyelitis, are common. As renal damage advances, the symptoms of renal insufficiency appear. There may be failure to gain, or even loss of weight. Loss of appetite and gastrointestinal upsets are common, as well as headaches and lassitude. With a lowered renal reserve these patients are more susceptible to intercurrent infections and often die of them. They may lapse into uremic coma. The true cause of the trouble may never be suspected, and the patient is often treated for pyelitis or chronic nephritis.

The diagnosis is established by making thorough urologic examination of all children who have chronic urinary troubles. Urethroscopic examination of these children will differentiate contractures, valves, hypertrophy of the verumontanum and cord bladder.

The treatment consists in removal of the obstruction when the condition of the patient permits. Infection and renal impairment may necessitate preliminary urethral catheter or suprapubic drainage for a variable length of time. Abundant

fluids and urinary antiseptics will hasten improvement. Blood transfusion is indicated in the anemic and those in generally poor condition. The hypertrophied verumontanum may be destroyed by any of the various punch instruments or by simple fulguration through the cysto-urethroscope.

SUMMARY

The congenital hypertrophy of the verumontanum here reported is of unusual configuration. This is one of the rarest obstructive lesions in the posterior urethra. A thorough review of the literature discloses only thirteen previously recorded cases. With careful attention to urinary symptoms and thorough urologic examination, this lesion should be discovered before renal damage has progressed to a point at which recovery is impossible. Treatment consists in proper preoperative preparation of the patient, followed by transurethral punch or fulguration of the verumontanum.

GLANDULAR PHYSIOLOGY AND
THERAPYCORTICOTROPIC (ADRENOTROPIC),
THYROTROPIC AND PARA-
THYROTROPIC FACTORS

JAMES B. COLLIP, M.D.

MONTREAL, CANADA

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—Ed.

THE CORTICOTROPIC FACTOR

It is to be noted that the word "corticotropin" (or "corticotrophin") is now being widely used as a descriptive term for the principle in the anterior lobe of the pituitary gland hitherto commonly spoken of as the adrenotropic factor. This is in line with the general recommendations of the Third International Conference on the Standardization of Hormones.¹

Physiologic Significance of Corticotropin.—There is now a mass of evidence that the maintenance of the cortex of the adrenal gland, in the morphologic as well as the functional sense, is dependent on the secretory activity of the normal anterior lobe of the pituitary. The atrophic adrenals of the completely hypophysectomized animal are not entirely functionless, however, since removal of them from rats hypophysectomized some weeks previously is not tolerated, and death ensues quickly. The function of the corticotropic factor is therefore to maintain the normal structure and function of the adrenal cortex.

Nature of the Corticotropic Factor.—Until such time as the hormones secreted by the anterior lobe are obtained in pure form, it will be impossible to know positively whether the substance acting on the adrenal cortex is a single substance having only this specific hormonal activity or a substance having other physiologic effects, tropic or otherwise, in addition to the

corticotropic property. Collip² reported that an isoelectric protein fraction obtained from an acid acetone extract had the properties of three hormones of the anterior lobe, namely, the growth-promoting factor, corticotropin and prolactin. The corticotropic activity of such extracts was shown to be fairly resistant to heating over a wide p_H range; the greatest stability was shown at p_H 3 to 5. Moon,³ using the Lyons method⁴ for the preparation of prolactin, showed that the material insoluble at p_H 6.5 is rich in corticotropin. This fraction had little prolactin activity, whereas a fraction obtained by isoelectric precipitation at p_H 5.5 was rich in prolactin but had a lower corticotropic content. It can be positively stated that corticotropin is separate and distinct from thyrotropin and from gonadotropin.⁵ All available evidence points to corticotropin being of protein nature.

Preparation of Potent Extracts of Corticotropin.—Although it has been my experience that most protein fractions obtained from extracts of anterior lobes have more or less corticotropic activity, I have found the following method satisfactory for the preparation of an extract rich in corticotropin and having a minimum of other principles of the anterior lobe.

Prime fresh tissue which has been largely defatted and dehydrated by extraction with alcohol is extracted twice with 5 volumes of 0.25 per cent acetic acid for each volume of original gland tissue used. The residues are then extracted a third time with 5 volumes of 0.25 per cent acetic acid, the mixture being heated to 75 C. for fifteen minutes, then cooled and filtered. The tissue residues are then suspended in 5 volumes of 0.25 per cent acetic acid and placed in a boiling water bath for four to six hours, the mixture being frequently stirred. The mixture is then filtered, and the filtrate is concentrated at low temperature and pressure until the volume is equal to the original volume of gland used. Sufficient concentrated hydrochloric acid is then added to make a 0.25 per cent concentration of this reagent, and the acidified mixture is placed in a boiling water bath for twelve hours. The extract at this stage is adjusted to p_H 4 and is ready for assay on the hypophysectomized rat. The salt content can be reduced by a short dialysis in cellophane. Fractionations of such extracts with a view to obtaining the corticotropic principle in purer form are being undertaken. An earlier observation that extracts obtained from simple hydrolysates of pituitary tissue (treatment on a boiling water bath for twelve to twenty-four hours with 10 volumes of 0.25 per cent hydrochloric acid) produced a number of physiologic effects when tested in the appropriate manner suggested the process described here for the preparation of extracts of corticotropin. In addition to retaining corticotropic properties, these simple hydrolysates were found to contain appreciable amounts of the metabolic, glycotropic and ketogenic substances. Feeding of hypophysectomized rats with such potent preparations has given no evidence that the corticotropic substance is active when taken orally.

Bioassay for the Corticotropic Substance.—In my opinion the most satisfactory method of assay for corticotropin is by the use of hypophysectomized rats. These animals should not be used until an adequate time has elapsed after hypophysectomy to insure that cortical atrophy has progressed to a marked degree. One month is a safe interval. In the method of assay originally described,⁶ one adrenal was removed from the test animal prior to beginning injections of the extract to be assayed. This was weighed and sectioned, and served as the control.

The injections were made twice a day for six days, and then the remaining adrenal was removed, weighed and sectioned for histologic study. It was suggested that a 50 per cent increase in weight together with positive histologic evidence of cortical repair should be considered a unit effect. A more extensive study of the response of hypophysectomized rats to a single corticotropic preparation administered at increasing levels of dosage showed that the accurate assay of such extracts for corticotropin is a very difficult matter.⁷ It is now believed that much greater uniformity can be obtained if restoration to normal or nearly normal size of the adrenals is accepted as a unit effect. It is suggested also that the period of injections be increased to ten days, that several animals be used and that biopsy is unnecessary.

The method of Moon³ for the assay of corticotropin consists in the treatment of normal 21 day old male rats for three days with the extract to be tested. Moon defined a unit as that amount of extract tested in this manner which caused a fifty per cent increase in the weight of the adrenals. An inert protein solution is used as a control in the Moon test. The Moon method of assay has much to commend it, and in the case of purified extracts there should be little danger of non-specific effects being obtained, for it is well known that adrenal enlargement due to cortical hypertrophy is readily obtained by treatment of normal rats with injections of a foreign protein.

General Considerations.—The ability of the normal anterior lobe to secrete corticotropin quickly in increased amounts in response to a great variety of so-called nonspecific agents would seem to constitute one of the chief arms of defense on the part of the body to injurious stimuli.⁸ As yet no success has been had in the demonstration of corticotropin in the blood. It would be of clinical value if more sensitive methods for the detection of this substance were available, so that actual assays of blood and urine in cases of Cushing's disease could be made.

No specific clinical value for preparations containing corticotropin has been demonstrated. There is the possibility that they might be of definite prophylactic value in cases of anticipated shock. There is likewise the possibility that in certain cases of Addison's disease there might be benefit from this form of therapy. Presumably, although there is no direct proof of it, the corticotropic substance causes the adrenal cortex to function to the full measure of its capacity. I have observed that the activity of hypophysectomized rats as measured in the running wheel cage is greatly increased after prolonged treatment with corticotropic extract. In view of the important, though as yet none too well defined, role which the adrenal glands play in carbohydrate and protein metabolism, as well as other phases of metabolism, a very important place must be assigned to the corticotropic hormone among the family of active principles of the anterior lobe.

THE THYROTROPIC HORMONE

Since the publication of the last edition of "Glandular Physiology and Therapy," in which knowledge of the thyrotropic hormone was reviewed, numerous papers have appeared dealing with this subject, but, as Van Dyke remarked in his excellent review of the physiology and pharmacology of the pituitary gland,⁹ recent investigations of the thyrotropic hormone from various biologic standpoints have yielded a disappointingly small crop of facts. Much of the effort has been expended in consolidating or extending slightly knowledge which was already available.

Heyl and Laqueur¹⁰ expressed the view that the principle responsible for thyroid enlargement differs from that which causes the histologic signs of hyperplasia. Heyl¹¹ emphasized that certain pituitary extracts cause obvious histologic signs of thyroid stimulation without increasing the weight of the gland, while other extracts elicit a pronounced increase in weight. He isolated a protein-free acetone-soluble pituitary fraction which had no effect on the thyroid by itself but caused marked enlargement of the gland when given in combination with a highly purified thyrotropic preparation that in itself caused only histologic signs of hyperplasia. He concluded that, in addition to the thyrotropic hormone, the hypophysis produces an activator responsible for the increase in weight. More recently, Billingsley,¹² studying this question in my laboratory, summarized his results as follows:

A number of thyrotropic extracts have been simultaneously assayed by the weight and histology of the guinea pig thyroid, and by the metabolic rate. No correlation can yet be expressed between these, except that increase in weight and hyperplasia apparently are associated more often than are either of these responses with an increased metabolism. The metabolic rate was found to respond most readily to thyrotropic extracts, and the guinea pig was more sensitive than the hypophysectomized rat. The anterior pituitary appears to have a two-fold action on the thyroid: one which influences the secretion of the thyroid hormone, the other to change the morphology of the gland. It is doubtful whether an identical mechanism is involved in each case, as indicated by comparative studies of the three assay methods.

Relations of the Thyrotropic Hormone to Other Hypophysial Principles.—Riddle and his co-workers¹³ showed that active gonadotropic pituitary preparations tested in pigeons do not always exert a thyrotropic effect. This indicates that the two hormones are not identical. Yet more recently, Tolksdorf and Jensen¹⁴ and Jensen and Tolksdorf¹⁵ came to the conclusion that the thyrotropic factor is identical with the interstitial cell-stimulating, or luteinizing, factor, since all pituitary fractions containing thyrotropin proved also to be active luteinizers and vice versa. Since purified thyrotropic preparations do not inhibit the action of insulin in the mouse, Jensen and Grattan¹⁶ concluded that the glycotropic action is not due to the thyrotropic principle, thus confirming the view of Young.¹⁷

Mechanism of the Thyrotropic Action.—Schneider¹⁸ and Schneider and Widmann¹⁹ observed that in the dog an extract containing thyrotropin increases the iodine content of the blood without a period of latency, thus differing from the action of thyroxine. Similarly in the guinea pig it leads to a rapid appearance of signs of

thyrotoxicosis. Although these signs are not evident before the thyroid undergoes hyperplasia, they develop much sooner than after treatment with thyroxine. These experiments suggest that the actions of the thyrotropic principle cannot be regarded as due merely to a liberation of thyroxine.

The fact that the thyrotropic hormone acts directly on the thyroid without any intermediary has been demonstrated by Eitel and his associates,²⁰ who found that an extract containing this factor when added to slices of dog thyroid increased the consumption of oxygen by the thyroid tissue and caused histologic changes similar to those usually seen in vivo.

Bioassay for the Thyrotropic Substance.—The Third International Conference on the Standardization of Hormones¹ agreed that extracts of the thyrotropic factor should be assayed in comparison with an international standard preparation which is distributed by the National Institute for Medical Research, Hampstead, London, England; 250 micrograms of this preparation are equivalent to 1 unit. It also agreed that only those tests can be considered safe which are based on actual observation of a stimulation of the thyroid, since other effects may be due to impurities in the extract.

In the axolotl, preparations of the thyrotropic substance induce metamorphosis, and this effect has been suggested as a basis for the assay of extracts for the thyrotropic principle.²¹

The frog tadpole has been used for the assay of preparations for the thyrotropic substance by Cuyler and co-workers,²² who standardized such preparations on the basis of an accelerating effect on metamorphosis.

The grass snake (*Tropidonotus natrix*) is a particularly good test object, according to Mason,²³ because its thyroid, unlike those of laboratory rodents, shows surprisingly little variation from the normal resting condition unless stimulated by pituitary extracts. The disadvantage of this method is that few laboratories are equipped with this experimental material.

The thyroid of the pigeon or of the dove likewise undergoes pronounced enlargement and shows histologic signs of hyperplasia after administration of an extract containing thyrotropin and is a suitable test object for assay purposes. It is important, however, to use either immature²⁴ or hypophysectomized²⁵ birds in order to make sure that the untreated controls have resting thyroids.

Immature chicks were first employed for such bioassays by Stimmel and associates,²⁶ who considered the decrease in the iodine content of the thyroid caused by the thyrotropin in an extract as an indicator of activity. Later Smelser²⁷ and Cope²⁸ used the increase in the weight and the histologic signs of hyperactivity elicited by the thyrotropic factor in the 1 day old chick as a basis for bioassay. Kabac and Liapin²⁹ made an accurate detailed study of this test object, using 5 to 6 day old chicks and estimating thyrotropic potency merely by the increase in thyroid weight. They stated: "As an arbitrary unit of thyrotropic preparation we designate the amount which brings

the weight of both thyroids of the chick to 8 mg. (on the average) after daily subcutaneous injections during five days. The experiments were carried out on 5 day old chicks, and autopsy was performed one day after the last injection." Bergman and Turner,³⁰ who employed the 1 day old white leghorn chick, emphasized that males are more sensitive than females. They defined the unit of thyrotropic activity as the total amount of extract administered subcutaneously once daily during four days which will cause a mean increase of 50 per cent (to about 5.4 ± 0.26 mg.) in thyroid weight in 20 chicks whose body weights average 55 ± 10 Gm. This unit corresponds to about one quarter of the guinea pig unit employed by the same investigators.

The guinea pig is the most commonly employed test object for thyrotropin. It represents an excellent test object, but a relatively young animal must be used in order to insure that the thyroid is in the resting stage before the thyrotropic preparation is administered. Aron³¹ and Aron and Klein³² stated that this is always the case in animals weighing less than 250 Gm. Loeser³³ used guinea pigs weighing 180 to 220 Gm. However, several subsequent investigators found that even in the small animal the thyroid may show signs of hyperplasia and of absorption of colloid under apparently normal conditions.³⁴ This variability of the normal thyroid structure induced Benazzi³⁵ and Junkman and Schoeller³⁶ to employ only animals weighing between 100 and 150 Gm. Aron³⁷ insisted, however, that the 200 Gm. guinea pig is suitable for assay purposes. He defined the unit as $\frac{1}{400}$ of the amount necessary to produce a 50 to 100 per cent weight increase in the thyroid of a 200 Gm. guinea pig twenty-four hours after this amount is administered in a single injection. Histologically, 100 units causes absorption of colloid and secretory phenomena in the enlarged acinous cells throughout the glandular parenchyma. Ten units exerts such an effect only in the central portion of the gland; 40 to 45 units represents the amount which is most easily gaged in a single test since it causes absorption of colloid, hyperplasia and the appearance of mitotic figures, but none of these signs is sufficiently marked to make it impossible to differentiate the effect from that of still higher doses. Well aware of the variability of the thyroid even among young normal guinea pigs, Paal and Kleine³⁸ described a "resting diet" which causes the thyroid to become entirely free of any signs of activity and thus makes it particularly suitable for bioassay purposes. De Fremery³⁹ advocated pretreatment with the thyroid depressing diiodotyrosine for the same reason. Krogh and associates⁴⁰ emphasized that a few vacuoles in the colloid of the thyroid gland cannot be considered as significant, and this is in agreement with my own observations. However, if this is kept in mind, 200 Gm. guinea pigs are quite suitable

for assay purposes, unless extremely small doses have to be detected. Such guinea pigs have also been used by Rowlands and Parkes,⁴¹ who adopted as a unit "the thyrotropic activity contained in an amount of extract which given daily for 5 days will cause the thyroids of the 200 Gm. guinea pigs to attain a weight of 60 mg., i. e., about double the normal." This method of assay has been accepted by Junkman and Loeser.⁴² Starr and Rawson,⁴³ Rawson and Starr⁴⁴ and Starr and others⁴⁵ measured the height of the thyroid epithelium and found it to be about 3.75 microns in normal females weighing 180 to 225 Gm. Using this "microhistometric" method, they assayed urine for its thyrotropic activity in various diseases by the increase in epithelial height which it produces. Heyl and Laqueur⁴⁶ insisted that the histologic changes, namely, the increase in the epithelial height and the vacuolation of the colloid, are the only satisfactory indexes of thyrotropic activity. They worked out a scale of six different stages of histologic signs of activity which they designated by the letters p to u. They termed "borderline dose" the amount which when given in two intraperitoneal injections on two consecutive days will cause in two thirds of the treated 150-200 Gm. guinea pigs a reaction "s" in the middle part of the thyroid within forty-eight hours. This reaction "s" is defined as a thickening of the cells in which the nucleus becomes round and the protoplasm develops on the distal pole of the cell to about the width of the diameter of the nucleus. In order to keep their unit as close as possible to those generally in use, they defined 1 guinea pig unit as one quarter of the "borderline dose." Wilcke⁴⁶ pointed out that it is important always to use the same fixative, since Susa's—which causes practically no shrinkage—makes the cells appear higher than does ordinary solution of formaldehyde U. S. P. diluted 1:10. He claimed that for the Heyl and Laqueur test the latter fixative is preferable. More recently Bergman and Turner³⁰ defined 1 guinea pig unit as the total amount of an extract containing the thyrotropic factor which when administered subcutaneously once daily on five successive days causes a mean increase of 50 per cent (to about 26.4 ± 1.63 mg.) in the thyroids of 10 male guinea pigs whose weights average 155 ± 15 Gm. According to Bastenie and Zylberszac,⁴⁷ 0.025 mg. of colchicine given for every 30 Gm. of body weight to 220-250 Gm. guinea pigs makes the mitogenic action of the thyrotropic extract readily detectable, since colchicine arrests mitotic division in the metaphase. This drug should be administered about nine hours before killing the animals.

The decrease in the iodine content of the thyroid furnishes another test of thyrotropic activity in guinea pigs.⁴⁸

The thyroid of the mouse is generally not considered to be a suitable test object for bioassay purposes, although Paal and Kleine³⁸ claimed that by using a special diet one may sufficiently repress the thyroid even in this species to make the effect of thyrotropic evident.

The thyroid of the rat is normally too variable to be useful for bioassay purposes. In hypophysectomized animals, on the other hand, the restoration of the atrophic epithelium gives a good index for thyrotropic activity.⁴⁹ The low basal metab-

olism of the rat is restored to normal by the thyrotropic factor, a change which has been advocated for bioassay purposes.⁵⁰ However, in view of the more recent discoveries showing that pituitary extracts other than those containing the thyrotropic principle may raise the basal metabolic rate, this method is not strictly specific.

Among other assay methods in which the rat is used should be mentioned that of Cuyler and co-workers,²² which is based on the action of the thyrotropic hormone in decreasing the iodine of the thyroid, and that of Karnofsky and Cronkite,⁵¹ based on the observation that this principle accelerates the eruption of the incisor teeth in the newborn rat.

Thyrotropic Content of Blood.—Van Caulaert and associates⁵² found that dog serum has the ability to stimulate the thyroid of the immature guinea pig. Fellingner⁵³ prepared an extract of dog blood which was definitely thyrotropic in the guinea pig.

Horse serum likewise shows thyrotropic activity.⁵²

Guinea pig blood, unlike that of most other species so far examined, does not contain any thyrotropic principle demonstrable by the guinea pig thyroid test.⁵⁴

Rabbit and rat blood are definitely thyrotropic in the guinea pig thyroid test.⁵² Aron⁵⁵ claimed that rat blood is particularly active in stimulating the thyroid of the immature rabbit.

Human blood is active in producing thyroid hyperplasia in immature guinea pigs.⁵⁶ Fellingner⁵³ showed that the active substance is readily extracted from the serum by 40 per cent acetone, from which it precipitates after the concentration is raised to 85 per cent. Aron⁵⁵ claimed that the thyrotropic activity may also be demonstrated by the effect of normal human blood on the thyroid of the immature rabbit.

Thyrotropic Content of Urine.—Emerson and Cutting⁵⁷ were unable to demonstrate any thyrotropic substance in dog urine using the guinea pig thyroid test. Similar negative results have been obtained with guinea pig urine by Aron,⁵⁴ who used the same test. Rat urine, on the other hand, is very active in stimulating the thyroid of the immature guinea pig.⁵⁸

Aron and collaborators⁵⁹ and Starr and associates⁴⁵ were able to demonstrate in the urine of man the presence of thyrotropic substance, using the thyroid of either the guinea pig or the rabbit as an indicator. Katzman and Doisy⁶⁰ stated that a modification of their tungstic acid process for the extraction of the gonadotropic factor from pregnancy urine is suitable for the extraction of a thyrotropic substance from urine. Nielsen⁶¹ claimed that the urine of some men stimulates, while

that of others depresses, thyroid development in the rabbit. Antognetti and Geriola⁶² and Emerson and Cutting⁵⁷ found normal urine quite inactive in the guinea pig thyroid test. Similarly, Jones⁶³ was unable to extract the thyrotropic principle from normal urine with a method which gave good recoveries when a pituitary extract containing this principle was simply added to urine. He concluded that either the hormone is not excreted in an active form or its chemical properties are so altered that it is not extractable with his method. Giedosz,⁶⁴ on the other hand, observed marked stimulation of the rabbit thyroid following administration of normal human urine. Sendrail and Tamalet⁶⁵ claimed that 15 cc. of normal urine (the amount employed for one 3 day assay) contains from 4 to 30 Aron guinea pig units.

Thyrotropic Content of Blood and Urine in Various Diseases.—In Simmonds's disease the thyrotropic activity of the urine is below normal as judged by the guinea pig thyroid test.⁶⁶

In acromegaly Fellingner⁵³ was able to recover thyrotropic substance in unusually large quantities from the blood, using his acetone extraction method. The urinary excretion of thyrotropic substance is increased in this disease, according to Nitzescu and Timus⁶⁷ and Sendrail and Tamalet,⁶⁵ who used the guinea pig thyroid test. The latter investigators obtained similar results in Cushing's disease. On the other hand, Jones,⁶³ who used the chick for assay, obtained negative results.

In myxedema and other types of hypothyroidism Aron,⁶⁸ Aron and Klein⁵² and Antognetti and Geriola⁶² obtained variable results, while Hertz and Oastler,^{49b} who followed restoration of the thyroid in hypophysectomized rats, and Rawson and Starr⁴⁴ and Sendrail and Tamalet,⁶⁵ who employed the guinea pig thyroid test, observed increased elimination of thyrotropic substance. Emerson and Cutting⁵⁷ using the latter test, found that following thyroidectomy the thyrotropic activity of the blood increases regularly, but such increase is only occasionally observed in spontaneous hypothyroidism. Jones,⁶³ who with his chick test could not detect any thyrotropic substance in the urine of normal persons or patients suffering from a variety of diseases, found a positive result in a case of myxedema.

The blood of patients with hypothyroidism is rich in thyrotropic substance, according to Fellingner,⁵³ Hertz and Oastler^{49b} and Bodart and Fellingner,^{66b} who also noted that following thyroidectomy the usually low thyrotropic activity of the blood of patients suffering from exophthalmic goiter undergoes a rapid and pronounced increase. It appears that the production of thyrotropic hormone is increased in thyroid insufficiency just as the output of gonadotropic hormone rises after the gonads are removed or have undergone involution.

In hyperthyroidism Aron^{68a} obtained variable results, while Krogh and Okkels⁶⁹ claimed that no thyrotropic activity can be demonstrated in the urine by the rabbit

thyroid test. Smith and Moore,⁷⁰ Antognetti and Gerioli,⁶² Emerson and Cutting,⁶⁷ Rawson and Starr,⁴⁴ Starr and other co-workers⁴⁵ and Sendrail and Tamalet,⁶⁵ all of whom used the guinea pig thyroid test, usually found subnormal quantities of thyrotropic substance in the urine, and in most cases this principle appeared to be entirely absent. Jones,⁶³ who used the chick test, likewise failed to detect excretion of thyrotropic substance. Drouet⁷¹ emphasized, however, that increased excretion of thyroxine, which may antagonize the effect of the thyrotropic hormone in the intact animal, may be the reason why most investigators were unable to detect the latter factor in the urine of hyperthyroid patients. He pointed out that negative results from urinary assays do not prove that thyrotropic substance is not excreted unless it is made certain that no substances antagonistic to the thyrotropic hormone are eliminated. It should be emphasized, however, that Hertz and Oastler,^{49b} who used hypophysectomized rats for their assays, were also unable to demonstrate thyrotropic activity in the urine of hyperthyroid patients, although in the absence of the pituitary the thyroid hormone would not have exerted an inhibitory effect. It is of interest, however, that, according to Nielsen,⁶¹ in exophthalmic goiter the urine actually causes atrophy of the epithelium in the rabbit thyroid, which suggests some antithyrotropic effect.

The blood of patients with hyperthyroidism likewise contains subnormal amounts of thyrotropic substance, according to the guinea pig assays of Fellingner⁵³ and Bodart and Fellingner.^{56b}

In obesity Merklen and co-workers⁷² invariably observed an increase in the elimination of thyrotropic substance, using the guinea pig test, while de Prat⁷³ obtained more variable results.

In various other diseases the results so far reported are too contradictory to justify detailed comment.⁷⁴ It is noteworthy, however, that, according to Aron,^{74a} in most cases the elimination curves of the thyrotropic and gonadotropic substances tend to run parallel.

Preparation of Active Extracts.—Greep⁷⁵ showed that a fairly complete separation of thyrotropic from gonadotropic substance could be obtained by treatment of extracts with benzoic acid. The thyrotropic factor was precipitated with the benzoic acid, and the gonadotropic factor remained in the filtrate.

Lambie and Trikojus⁷⁶ have recently described a method of extraction and purification of the thyrotropic principle. Collip⁷⁷ has found that, in addition to the thyrotropic substance which is obtained in primary dilute acetic acid extracts, an isoelectric protein fraction can be prepared from the gland residues which is highly potent in thyrotropic properties. Moreover, guinea pigs treated daily with the latter fraction may not show

resistance to it for many months. This is confirmatory of the results of Werner,⁷⁸ who found that thyrotropic extracts prepared by different methods differed widely in their ability to cause development of the refractory state in guinea pigs.

Effect of Iodine on Action of Thyrotropic Hormone.—Friedgood⁷⁹ has reported that the administration of sodium iodide to guinea pigs receiving an extract containing the thyrotropic factor caused a remission of the symptoms of hyperthyroidism. Anderson and Evans⁸⁰ observed that in guinea pigs potassium iodide may prevent the metabolic action of thyrotropic extracts (perhaps because it prevents the discharge of thyroxine) without interfering with the effect on the thyroid itself. Franck⁸¹ found in guinea pigs treated with an extract of the anterior lobe that the basal metabolism decreased after an initial increase. During the period of decreased basal metabolic rate the thyroid showed storage of colloid. This storage appeared simultaneously with an enlargement of the Golgi apparatus and was considered to be due to a special action of the thyrotropic principle. Iodine administered to such animals prevented both the initial rise and the eventual fall in the basal metabolic rate. According to Franck, extracts of the anterior lobe cause degranulation of the eosinophils and an increase in the number of basophils in the anterior lobe of the guinea pig. These effects are inhibited by iodine. He concluded that the basophils of the pituitary secrete a thyrotropic hormone which stimulates storage of colloid in the thyroid follicles. The secretion of this hormone is prevented by the administration of iodine.

THE PARATHYROTROPIC HORMONE

Although the existence of a parathyrotropic hormone has not been proved as yet and may be regarded as rather doubtful, certain clinical and experimental evidence now available concerning this question will be discussed.

Parathyroid Tumors.—Adenoma of the parathyroids has repeatedly been observed in association with hypophysial tumors,⁸² a fact which suggests that a close relationship exists between these two glands.

Hypophysectomy.—In the dog Aschner⁸³ was unable to detect any change in the parathyroids following ablation of the hypophysis, while Koster⁸⁴ claimed that the parathyroids were invariably subnormal in size. Housay and Sammartino⁸⁵ stated that degenerative lesions

and necrosis of the parathyroids may be observed in 66 per cent of all hypophysectomized dogs, while they are seen in only 10 per cent of the normal controls. After lesions of the tuber cinereum they were noted in about 41 per cent of the cases.

In the rat Smith⁸⁶ claimed to have noted atrophy of the parathyroids following hypophysectomy.

Hypophysectomy and Pancreatectomy.—The degenerative changes which occasionally occur following hypophysectomy are much more commonly observed in the dog in which the pancreas is also removed. Mere removal of the pancreas, however, does not elicit such changes except in rare cases.⁸⁷

Hypophysial Extracts.—In the cat Anselmino and co-workers⁸⁸ claimed that the so-called parathyrotropic extracts of the pituitary cause hyperemia and histologic signs of increased activity in the parathyroids without actually increasing their size.

In the dog, following treatment with hypophysial extract, enlargement of the epithelial cells, follicle formation and hyperemia have been observed without enlargement of the total volume of the gland,⁸⁸ and the structural changes were often accompanied by hypercalcemia.⁸⁹ Recently Ham⁹⁰ reported changes supposedly characteristic of the parathyrotropic hormone in the parathyroids of dogs treated with pituitary extract.

In the guinea pig Anselmino and associates⁸⁸ also claimed to have seen parathyroid stimulation after the administration of pituitary extract.

In the dwarf mouse Kemp and Marx⁹¹ claimed to have seen parathyroid enlargement following administration of a preparation containing the growth-promoting factor of the anterior lobe.

In the rabbit Hertz and Kranes,⁹² Anselmino and associates⁸⁸ and Cattaneo⁹³ observed enlargement and changes after treatment with various pituitary extracts, which they interpreted as characteristic of the parathyrotropic hormone.

In the rat Anselmino and co-workers⁹⁴ claimed to have obtained particularly obvious parathyroid enlargement accompanied by hypercalcemia following treatment with their extract of the parathyrotropic factor, and Hoffmann and Anselmino⁸⁹ emphasized that the hypercalcemia is prevented by parathyroidectomy.

It should be emphasized, however, that the existence of the parathyrotropic hormone has by no means been proved.⁹⁵

Special Clinical Article

CHEMOTHERAPY IN UROLOGY

CLINICAL LECTURE AT NEW YORK SESSION

EDWARD N. COOK, M.D.

ROCHESTER, MINN.

As in all fields of medicine, the advent of sulfanilamide and its derivatives has been a welcome addition to the armamentarium of the urologist. Almost a decade ago chemotherapy in urology made its first real step forward with the use of the ketogenic diet in the treatment of infection of the urinary tract. This rather cumbersome therapeutic agent was shortly followed by the discovery that mandelic acid is of equal value and much easier to administer. These therapeutic measures depended for their effectiveness on a certain concentration of an organic acid in the urine at a pH level below 5.5. Even when the desired conditions were met, many infections did not respond to such therapy. It was evident that, when a gram-negative bacillus or *Streptococcus faecalis* was present, bacteriostasis was the rule and the organism could be eradicated. However, when *Staphylococcus aureus* or *albus*, *Micrococcus* or the hemolytic or green-producing streptococcus was present these agents were not effective in destroying the organisms. The need for an adjunct to the treatment of such urologic conditions was apparent and the early reports concerning the use of sulfanilamide and its derivatives have stimulated investigation in the field of infections of the urinary tract.

The effectiveness of the sulfonamide compounds in the treatment of bacterial infections has entirely changed the practice of therapy within a few years. Owing to the chemical reactivity of the parent substance, countless derivatives have been synthesized and their therapeutic action has been determined. It is not within the scope of this paper to go into the history of the development of these compounds. Neither is it possible to discuss the entire gamut of those derivatives of sulfanilamide which have been used in the treatment of urologic diseases associated with or caused by bacterial invasion.

Before the actual use of these compounds in urology is discussed, a word or two concerning the mode of action seems indicated. Undoubtedly a direct action on the organism does take place both in vitro and in vivo. In urology the actual presence of the drug in the urine in the free form undoubtedly is a factor in its effectiveness, and its presence in tissue fluids enables it to reach the deeper seated infections. Whether or not the sulfonamide compounds have any effect on the immune processes of the body has been a point of controversy. The body defenses are important and necessary factors in the final curative effects, but whether phagocytosis is truly stimulated by the administration of these drugs is not definitely known at this time. More recently the bacteria-destroying property of the drug has been attributed to the accumulation of hydrogen peroxide due to the inactivation of catalase by the drug.

Turning now to the discussion of the clinical aspects of the use of the sulfonamide compounds, the main factors influencing the results obtained are the type of

organism present, the type of case being treated, the mode of administration and dosage used, and the patient's ability to tolerate the drug as evidenced by signs of toxicity.

TYPE OF ORGANISM

Early in our work from experimental and clinical data my associates and I became aware of the fact that sulfanilamide and its more closely related derivatives, such as disulfanilamide, and sulfanilyl-sulfanilamide, were the gram-negative bacilli and the beta-hemolytic streptococcus. The same was true for azosulfamide. The organisms of the genus *Proteus* have always presented a most difficult problem. Because of their urea-splitting property, chemotherapy requiring acidification of the urine was usually of little value because of the difficulty in producing the desired acidity. The sulfonamide compounds have been most useful in treating infection produced by this organism because these drugs in most instances are more effective in an alkaline medium. *Staphylococcus*, *micrococcus* and *Streptococcus faecalis* were usually not affected by these drugs with the exception of dimethyldisulfanilamide, which has never been marketed in this country because of the too frequent complication of peripheral neuritis largely involving the motor nerves. The gonococcus was attacked with considerable ease in the properly managed infection, but in many instances "sulfanilamide-resistant" cases were reported and the need for an additional chemotherapeutic agent became apparent.

The early experimental work with sulfapyridine showed little advantage in the treatment of infections of the urinary tract caused by the gram-negative bacilli or the streptococci. However, it was of some value in the group caused by the staphylococci. Because of the early reports concerning its action on the pneumococcus we used it in the treatment of infection produced by a similar organism, the gonococcus. Its efficacy here was much greater than that of sulfanilamide.

More recently we have had the opportunity to use another derivative, sulfathiazole, in the treatment of infections of the urinary tract. Again the usual gram-negative bacilli are destroyed by its administration. Of great interest to all of us is the fact that this drug is effective in eradicating staphylococcus and micrococcus, which were so resistant to the other sulfonamide compounds. The beta hemolytic streptococcus does not respond as well and in only about 30 to 40 per cent of the early cases was *Streptococcus faecalis* destroyed. Recently Helmholz has shown experimentally that the level of the p_H of the urine in vitro has a marked effect on the bactericidal property of sulfathiazole against *Streptococcus faecalis*. At a p_H of 5.0 a concentration of from 25 to 50 mg. per hundred cubic centimeters destroys the organism. As the degree of acidity decreases, a greater concentration of the drug becomes necessary until, at a p_H of 7.5, 200 mg. per hundred cubic centimeters will do little more than produce some bacteriostasis. We have been able to confirm this clinically.

Sulfathiazole, however, is the drug *par excellence* in the treatment of gonorrhea. To date we have treated only a group of sixteen patients suffering with this disease, but in all of them the gonococcus has been effectively destroyed within one week of the start of the administration of sulfathiazole. In the usual case the discharge disappears within three or four days and the two glass test shows both glasses of urine to be clear macroscopically and microscopically. At this time

the prostate is massaged and, if the secretion shows evidence of infection, regular prostatic treatment is instituted consisting of massage, irrigations and instillations as needed. If the prostatic secretion is negative, it is rechecked in another two or three days and if it still does not show any evidence of infection no further examination or therapy to the prostate is indicated.

TYPE OF CASE

Knowing the exact pathologic condition present in each case of infection of the urinary tract is just as important as knowing the exact organism responsible for the infection. By no means do I wish to imply that each patient who presents himself with the complaint of burning and frequent urination should be submitted to an extensive urologic investigation. Beyond any doubt, from the history and the initial examination our clinical judgment will decide its need in most instances. However, if after one or two satisfactory courses of chemotherapy the desired improvement and cure have not been gained or if repeated reinfection occurs, we must make certain that we are not dealing with complicating pathologic conditions such as stone, tumor, obstruction, foreign body or deep seated infection producing cicatrization and scarring of some part of the urinary tract.

Experience has taught us that in the simple uncomplicated cases of infection of the urinary tract almost any of the sulfonamide compounds is effective in destroying the disease in more than 90 per cent of the cases. Interestingly enough, this holds for the cases in which the infection is in the kidney as well as in those cases in which it is confined to the bladder alone, provided there is no cicatricial deformity or complications previously described. Early in our efforts we noted the inhibiting effect of chronic prostatitis on the efficacy of urinary antiseptics. The percentage of cases in which cures are effected is reduced almost a half unless the prostatic infection is adequately treated at the time of the drug therapy. It is not the rule that any of the sulfonamide compounds is regularly useful in treating nonspecific prostatitis. In certain cases in which the infecting organism in the urine can also be recovered from the prostatic secretion, good results may follow sulfanilamide therapy. Little more need be said concerning the usual complicating pathologic conditions found and the treatment required in certain infections of the urinary tract. Stone, foreign bodies and tumors should be removed; obstruction should be relieved. Unless this is done, only rarely shall we find the sulfonamide compounds of any use in the treatment of associated infection.

When the infection in the kidneys is of long standing and considerable cicatricial deformity, and perhaps caliectasis, have been produced, the problem of therapy is considerably more difficult. As mentioned previously, the action of the drug depends on its presence and concentration in the body fluids as well as in the urine. However, many observers believe the latter fact is the most important and consequently to obtain a bacteriostatic or bactericidal action in the urine we must have a kidney functioning well enough to excrete the drug. An infected, poorly functioning kidney will be benefited only to the extent to which the drug can be excreted by it. A most interesting observation has been that the sulfonamide compounds, and particularly azosulfamide, may be administered in moderate dosage to such patients with little chance of injuring these poorly functioning kidneys. This is not true when using

mandelic acid or the ketogenic diet, as with the latter therapeutic agents function is usually more impaired and the treatment must be stopped. More recently we have been using some of the newer sulfonamide compounds, particularly sulfathiazole, and, much to our surprise, have found the last mentioned drug to be more effective in the chronic case of pyelonephritis in which the kidneys show the typical chronic inflammatory changes such as cicatricial deformity and caliectasis with slight to moderate reduction in function as evidenced by the excretory urogram.

MODE OF ADMINISTRATION AND DOSAGE

The sulfonamide compounds when given to man may be given orally or parenterally. These drugs are almost entirely eliminated in the urine, partly in a free state and partly in a conjugated form, as an acetylated compound. It is the free form which exerts the bacteriostatic and bactericidal effect. When given orally the rate of absorption of these drugs varies with different cases and with the drug used, but usually two or three days is required to establish equilibrium between the amount ingested and the amount excreted. Somewhat less time seems to be necessary when sulfapyridine or sulfathiazole is administered. In certain instances oral ingestion is impossible for various reasons, and in these cases parenteral injection has been of great value. Sulfanilamide powder may be prepared in an 0.8 per cent solution in physiologic solution of sodium chloride and given subcutaneously. In this way a patient may be given more than 100 grains (6.5 Gm.) of the drug daily with little difficulty. The sodium salt of sulfapyridine may be given intravenously and some observers have recently shown that sulfathiazole may be given in the same way. The intravenous use of these drugs is useful in building up rapidly an appreciable level of the drug in the blood, particularly for those patients who have difficulty in taking the drug by mouth. The disadvantage, however, is that while the concentration in the blood is built up rapidly it also decreases rapidly and frequent administrations are necessary if an adequate concentration is to be maintained.

Clinically I do not feel that determinations of the level of these compounds in the blood are necessary in the satisfactory handling of patients suffering with infections of the urinary tract. Many estimations have been made and only in rare instances have I seen concentrations more than from 5 to 6 mg. per hundred cubic centimeters with the dosage usually used. I believe that a greater concentration in the blood is rarely needed to destroy an existing infection.

In the field of infection of the urinary tract the oral and subcutaneous administrations are usually sufficient. Various dosage levels have been suggested by many observers. However, it has been my experience that in the majority of instances sulfanilamide and its more closely related derivatives need seldom be given in a dosage greater than 40 grains (2.6 Gm.) daily. This is given in equal doses four times a day. The ease of administration may be enhanced by supplementing each dose with a similar quantity of sodium bicarbonate. The addition of the latter drug may have an additional value in that Helmholz and Sickler have shown that the efficacy of sulfanilamide in the urine is increased at a pH level of 7.5. If sulfanilamide must be given parenterally, a somewhat greater dosage is advised, as previously mentioned.

Azosulfamide, while not as effective as sulfanilamide in equal doses, is of great value in urologic work. It is

given in a dosage of 60 grains (4 Gm.) daily and may have to be used over a somewhat longer period. Usually sulfanilamide or azosulfamide is given for a period of from eight to fourteen days. At the end of that time we have deemed it advisable to stop the drug whether the urine has been sterilized or not. An intervening period of two or three weeks followed by a second course of the medication will frequently bring about the desired results. In a number of cases we have found a second and third course of the drug necessary before sterilization takes place.

Sulfapyridine has not been used extensively in this country in the treatment of the usual bacillurias and cocciurias. Foreign observers report little advantage for it over sulfanilamide in such cases. However, in the treatment of gonorrhea it has been of great value. We have regularly used a dosage of 45 grains (3 Gm.) daily for a period of from ten to fourteen days. If the urine in such cases is not grossly clear and the urethral discharge is not stopped within three days the dosage is increased to 60 grains (4 Gm.) daily. The drug is best given with milk and this will relieve much of the nausea attending its use.

More recently another derivative of sulfanilamide, namely sulfathiazole, has been added to our armamentarium. The original dosage used was 60 grains (4 Gm.) daily but recent work has led me to believe that in most cases 45 grains (3 Gm.) will be sufficient. This is given in divided doses by mouth and if it is at all nauseating its administration is likewise eased by giving it with milk. As previously mentioned, it has proved to be of inestimable value in the therapy of staphylococcic and gonococcic infections. In the latter conditions I believe that 60 grains (4 Gm.) daily is advisable and I have continued this for a period of from ten to fourteen days, although in all our cases the discharge was stopped and the urine was clear in from three to four days. Local treatment is instituted as previously described under the discussion concerning sulfapyridine.

TOXIC MANIFESTATIONS

When one surveys the many contributions to the literature with regard to the untoward reactions noticed following the administration of the sulfonamide compounds, the need for careful observation of each patient taking the drug becomes apparent. It is true that in the management of infections of the urinary tract these untoward reactions are less frequent than in the general field of therapy. Signs of toxicity may be due to sensitivity or idiosyncrasy to the medication. While the latter is more severe, it is less common. Sensitivity to the drug is more frequently noted to a greater or lesser degree and is almost always related to the dosage used and the total amount administered.

I have made it a practice never to administer any of the sulfonamide compounds unless the patient can be seen in from twenty-four to forty-eight hours. With this scheme I feel that we have been able to avert some of the more serious reactions frequently experienced. No doubt the main reason for the relative infrequency of the more serious toxic manifestations is the reduced dosage which has been found satisfactory in our field. Headache, malaise, vertigo, tinnitus, anorexia and nausea are frequently seen to a mild degree and usually will disappear on the third or fourth day the drug is taken. Patients with these mild to moderate symptoms should be observed closely, as these symptoms may be the precursors of more serious reactions. Cyanosis of a mild degree may be disregarded, but if it increases I

believe this is enough to warrant stopping the drug, as it may be an indication of an impending blood dyscrasia. It has been stated that sulfanilamide injures the blood-forming organs in from 4 to 5 per cent of cases. Hemolytic anemia of the acute and chronic form has been frequently reported, the acute form coming on within the first week of therapy and the chronic form not being seen for two or three weeks after treatment has begun. The development of granulocytopenia usually comes after the administration of large doses or prolonged treatment. It is a severe reaction and usually fatal. Unquestionably many of these blood conditions following administration of sulfanilamide could be avoided with more careful and frequent observation of patients. I am certain that a few extra blood counts when cyanosis is developing would often aid in averting these serious complications.

Dermatitis is a rather frequent complication and is of two types, the one localized to the exposed parts and the other a more general eruption over the entire surface of the body. The former type is caused by an increased sensitivity of the skin to light as a result of ingestion of the drug. The latter type is a toxic dermatitis. The presence of either form requires stopping the drug, but it can be resumed at a later date in the former type if the patient is instructed to keep out of the sunlight while taking the drug. With all the sulfonamide compounds I have found the dermatitis to be more likely to occur during the second course of the administration of these drugs, particularly if the second course of the drug is begun within eight days of the previous course. A certain sensitization must occur and the same fact has been noted by other observers. By prolonging the period between courses I feel that the frequency with which dermatitis occurs has been definitely reduced.

Sulfapyridine produces in general the same toxic disturbances as sulfanilamide but these are less severe with few exceptions. Nausea is more common but can frequently be relieved by taking the drug with milk. Gastric disturbances following the ingestion of sulfapyridine present but a small problem to the urologist as compared to the general physician because the former rarely needs to use large doses. A very important toxic sign is evidence of irritation along the urinary tract. As with sulfanilamide, an acetylated derivative of sulfapyridine is formed within the body and excreted in the urine. Crystals of this substance are frequently found in the urine of patients taking the drug and no doubt produce hematuria, either gross or microscopic, in approximately 5 per cent of cases. This complication is not important usually, but cases have been reported in which necropsy has shown complete casts of the calices, pelvis and ureters when large doses of the drug have been taken.

Azotulfamide and sulfanilyl-sulfanilamide produce similar toxic reactions to sulfanilamide itself but as a rule these side-effects are of a milder degree. Dimethyl-disulfanilamide and more recently sulfamethylthiazole, two drugs of generally lessened toxicity, have had to be discarded because of the frequency with which peripheral neuritis has appeared after their use. The same complication has occurred after sulfanilyl-sulfanilamide, only much less frequently.

For some months I have been using sulfathiazole and find it much less toxic than the parent substance. The usual symptoms seen after ingestion of sulfanilamide appear here also, but they are less severe. As yet I know of no disturbances simulating the nerve lesion

previously mentioned as following the administration of sulfamethylthiazole. Dermatitis does occur but again I have been able to decrease the incidence of this complication by prolonging the first course of the drug and waiting at least two weeks before again giving it in any dosage.

SUMMARY

Sulfanilamide and its related compounds have proved of inestimable value in the treatment of infections of the urinary tract.

In those cases in which the infection cannot be eradicated by chemotherapy, a thorough and complete search by a competent urologist should be advised because of the frequent association of complicating pathologic conditions such as stone, tumor, obstruction or cicatricial deformity.

A moderate sized dose is all that is needed in the treatment of most urologic infections.

The closest observation of patients taking these drugs is needed. The use of the sulfonamide compounds in the treatment of infection of the urinary tract is still in its early stages and true evaluation will necessitate continued experimental and clinical work in order to determine their efficacy in infections of certain types produced by the various organisms.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

McCURDY MODEL GAS MACHINE ACCEPTABLE

Manufacturer: Safety Gas Machine Company, Inc., 1163 Sedgwick Street, Chicago.

The McCurdy Model Gas Machine is designed for the administration of inhalation anesthesia, utilizing D cylinders of oxygen, carbon dioxide, nitrous oxide and ethylene with provision for an extra tank of each gas to be attached to the machine. An efficient reducing valve is connected with the yokes for each cylinder. Leaks from cylinder to cylinder cannot occur. The Augustana Model Gas Machine made by the same manufacturer, which is on the Council's list of accepted devices, is similar to the McCurdy Gas Machine.

Gases are admitted for delivery singly or in combination into a central mixing chamber through individual visible water manometer gages. The flow of each gas may be regulated by individual needle valves to obtain the desired proportion. The graduations on the manometers are apparently in gallons per hour.

A large lever on the top of the mixing chamber may be moved from the "on" to the "off" position if it is desired to by-pass the flowmeters for all gases. In the "on" position, needle valves on the top of the mixing chamber are used to regulate flow. In the "off" position, coarse flow valves on the base of the machine regulate the flow, without any registration of volume by the flowmeters. Apparently the latter provision is to enable the administrator to obtain the larger volumes necessary when using the apparatus for a semiclosed administration of gases, with the flutter valve in the circuit open to allow for exhalation.

A by-pass valve provides a quick source of oxygen. An ether vaporizer which is attached near the outflow from the machine permits the addition of varying percentages of ether to the gas mixture.

McCurdy Model Gas Machine.

The remainder of the apparatus consists of a so-called circle filter or a carbon dioxide absorption unit. The large canister in the circuit may be cut out at will, and an exhalation valve in the circuit may be kept closed for completely closed technic or opened for semiclosed technic.

The mask furnished with this machine is a transparent plastic type with rubber cushion for comfort and good fit. The breathing bag is of about 10 liters capacity. The whole apparatus rests on a substantial pedestal with rubber tired casters. A length of chain attached to the base trails on the floor, apparently for grounding purposes. The apparatus moves readily in spite of its weight.

The resistance to breathing is in the order of 3.5 cm. of water both on inspiration and on expiration, which is comparable to that found in most circle filters and is accounted for by the length of tubing and the inherent resistance to movement of the type of one-way valves incorporated. This resistance might be of some significance during anesthetization of a debilitated individual, especially during a long operation. It is doubtful whether any decrease in resistance could be obtained except by some radically different method of circulating gases.

Absorption of carbon dioxide is quite efficient, as shown by actual gas analysis; that is, compared to other circle filters and to and fro filters which we have tested. It must be recognized that no absorption units in use today reduce carbon dioxide to atmospheric levels.

The Council's clinical investigation revealed that in the hands of the skilled anesthetist the aforementioned gases and their combinations with ether may be efficiently administered with the McCurdy Model Gas Machine.

The Council voted to accept the McCurdy Model Gas Machine for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

ORGANIC MERCURIAL COMPOUNDS AS BACTERICIDAL AGENTS

Although mercury, as simple and as complex compounds, has enjoyed popular use for the destruction of bacteria since the time of Koch, there is still no uniformity of opinion as to its true value. Whether this has arisen from lack of adequate controls or from misinterpretation of reported results, the fact remains that simple and complex mercury compounds still enjoy widespread popularity and enormous quantities are sold yearly.

In 1881 Koch reported that mercury bichloride was an effective agent in destroying the spores of even the most resistant bacteria, but in 1889 Geppert showed that the substance was poorly bactericidal but markedly bacteriostatic. In spite of the carefully controlled work of Geppert, mercury bichloride has remained in constant demand, and as each new mercurial is advanced for its antibacterial effects there is a renewed interest, often accompanied by an increasing false sense of security. In recent years solutions of mercurial compounds in which mercury has been combined with dye or other organic radicals have been advocated; because of their popularity they have largely replaced mercury bichloride, mercuric cyanide and mercuric iodide (or potassium mercuric iodide) for their reaction against infective agents; but even reports on these newer agents are not in harmony.

DEFINITION OF TERMS

No doubt one of the reasons for the existing confusion lies in the looseness with which such terms as "antiseptic," "sterilize," "germicide" and "bactericide" are used. According to an editorial which appeared in THE JOURNAL in 1927, a germicide is

defined in current medical textbooks as a "substance or agent that destroys micro-organisms so that they will not grow when placed in appropriate culture mediums"; an antiseptic is defined as a "substance that hinders or prevents the growth of micro-organisms but does not necessarily destroy their vitality."

As long ago as 1910 the Council on Pharmacy and Chemistry asserted that:

It seems of the greatest importance that antiseptic power be not mistaken for germicidal power and that physicians should be correctly informed as to these properties of disinfectants recommended to them, so that they may decide for themselves in every given case which action they wish to produce.

The term sterilization is often used, even by the physician, to connote germicidal or bactericidal or sometimes just bacteriostatic properties. In 1936 the Council formally went on record as "disapproving of the use of the terms 'sterile,' 'sterilize' and 'sterilization' in a bacteriologic sense other than in their correct scientific significance; i. e., meaning the absence or destruction of all micro-organisms." Many feel that they are "sterilizing" an instrument by immersing it for a definite period of time in some mercurial solution. Such an assumption is not necessarily valid, as no evidence has yet been offered¹ which is conclusive and accepted by all that there exists any mercurial compound which can be relied on to destroy the spores of anaerobic bacteria. Limitation exists even with nonsporulating bacteria.

About thirteen years ago the U. S. Bureau of Chemistry, which at that time was charged with the enforcement of the Food and Drug Act, came to the conclusion that the term "antiseptic," when used in the labeling of a medicinal product, was objectionable unless the preparation when used as directed would actually destroy micro-organisms. The Council on Pharmacy and Chemistry regards an antiseptic as having more disinfectant than germicidal properties and not to be necessarily highly germicidal.

In the Insecticide-Disinfectant Code² a disinfectant is defined as follows:

The term disinfectant as used herein means any chemical or drug or combination of chemicals or drugs intended to destroy one or more kinds of disease germs or other harmful micro-organisms (not including bacterial spores) when applied to all inanimate objects that might harbor disease germs.

EVALUATION BY THE PHENOL COEFFICIENT AND OTHER TESTS

Another factor which has been of little service in clarifying the picture is the use of the phenol coefficient test as a method of evaluating the antibacterial properties of the mercurials. Attention was drawn to this by the Council in a report of its 1939 annual meeting³ when the members cited the following paragraphs from circular 198 of the U. S. Department of Agriculture:

There are certain types of germicidal agents, such as many of the mercury compounds, which give very high results by phenol coefficient tests. Due to the high inhibitory value of such substances in preventing growth in the subcultures, these figures are frequently misleading. For germicides used in the disinfection of such objects as surgical instruments, this is of particular importance and must be taken into account. Failure to appreciate this characteristic of certain compounds is much more likely to lead to error when *Staphylococcus aureus* is used rather than *Eberthella typhi* as the test organism. That false values may not be obtained for products of this type, or for any other disinfectant giving suspiciously high results, the subcultures should contain very large amounts of medium or they should be retransferred by carrying at least four loopfuls from the first subculture to a second tube of broth, as recommended by Shippen.

Other groups of disinfectants in common use, for which the phenol coefficient method of testing is not well adapted, are those compounds containing chlorine as the active agent, as well as the oxidizing agents in general. These are affected so materially by the presence of organic matter that a phenol coefficient statement may grossly misrepresent their value under practical conditions of use and is very apt to be misleading to the consumer when placed on the label.

The Council pointed out that an unduly high and misleading phenol coefficient is given in the case of mercurial disinfectants because the retransfer method was omitted, and any bacteriologic

tests for mercurial compounds alleging bactericidal properties should be made under conditions of actual application to supplement a test under simplified and arbitrary conditions. For instance, it has been found that mercurials are rendered completely inert bacteriologically by the addition of relatively larger amounts of normal horse serum. To get a therapeutic result even in serum would require many times the lethal dose of the mercurial. This inactivation by serum has been studied quantitatively by Smith, Czarnetzky and Mudd.⁴ In view of such reports, the Council declared the phenol coefficient to be an inadequate basis for judging the antiseptic value of nonphenolic agents needing to be supplemented by tests under conditions of actual use.

The principle of the phenol coefficient test used in 1903 by Rideal and Walker is essentially that employed at present. The phenol coefficient is that figure which is obtained on dividing the greatest dilution of the disinfectant killing test organisms in a definite period of time by the greatest dilution of phenol killing in the same interval of time. There have been many attempts to improve on the original method but none have attained perfection. Knighton⁵ compared the Hygienic Laboratory method and the Food and Drug Administration phenol coefficient method with the Rideal and Walker method and demonstrated the variations in technic designed to simulate practical conditions. In addition, he reviewed other variations such as using different test organisms, adding sterilized fecal material and serum, wet and dry filter paper method, agar plate method and agar cup plate test. Not one has proved to be ideal.

Since the phenol coefficient test is of dependable value only for comparison of the efficiency of phenol and phenol-like compounds and does not take into account the destruction of bacterial spores or the part which organic material may play, various totally different procedures have been devised⁶ but little more success has been met, since in vitro experiments will not necessarily give the same experimental results in vivo or even when repeated in vitro.

Many tests are misleading because of misinterpretation of the results. According to Knighton,⁵ some of the faults are due to (a) comparing the usable dilution with the germicidal strength, (b) testing the material on only one or two types of organisms or, in the case of spore-forming bacteria, on the organisms in their vegetative form rather than on the spores, (c) failing to account for possible deterioration in volatile substances, (d) ignoring the fact that certain chemicals may behave differently when diluted or when combination occurs with other substances which are present, (e) confusion of terminology and (f) lack of appreciation, especially with the mercurial compounds, of the bacteriostatic substances giving exaggerated bactericidal value when the phenol coefficient test is used. Neutralization of the inhibiting factor by subculture, washing or a neutralizing agent must first be carried out to prevent false bactericidal values.

Thaysen⁷ criticized the British Standards Institution's technic of the Rideal-Walker test for the evaluation of antiseptics because of difficulties in obtaining consistent results which arise from the survival of a few of the bacteria when exposed to the solution to be tested. Transference of at least one cell to the growth tubes may be problematic on account of a too small number of surviving cells. To ensure transfer of the organisms would require transfer of much larger quantities of the solution than is required by the test. The British Standards Institution test requires an exposure of eight minutes, the Chick-Martin test an exposure of thirty minutes. However, the latter gives more consistent results than the Rideal-Walker test with a ten minute exposure. Complete destruction of *Bacterium typhosum* in phenol solutions requires one hour.

Apart from the lack of accurate tests for determining the true comparative bactericidal value of compounds in test tubes there remains the fact that any antibacterial effect observed in vitro will not necessarily be the same on living tissue. Factors here which will determine the eventual outcome include bactericidal action of normal blood, previous history of disease, type of organism, virulence, number of organisms present, presence of organic material and the tissue toxicity of the antibacterial agent. Because of the part played by phagocytosis in combating infection, Welch and Hunter⁸ made use of this phenomenon in developing a method of testing antiseptics by determining what they called a toxicity index, which is the highest dilution of antiseptic toxic for tissue (determined by the inhibition of phagocytosis) divided by the highest dilution capable of killing the test organism. This procedure is reminiscent of that performed by Salle and his associates,⁹ who determined a toxicity index by using chick embryo tissue. A summary of the tissue toxicity tests has been made by Knighton⁵ in an attempt to point out that there is a need for tests to determine any deleterious effect on the skin, as well as the relative efficiency of the substance tested.

Another factor which may influence the effectiveness of a germicide is the acidity. Bittenbender and his co-workers¹⁰ point out that acidity has been known since the time of Pasteur to affect the growth of some bacteria. Previous work¹¹ showed that a change in hydrogen ion concentration affected the action of some organic mercury compounds, phenolic compounds and other antibacterial agents. This work was confirmed by Bittenbender¹⁰ using *Staphylococcus aureus* and *Escherichia coli* as test organisms. The agents showed increased potency with an increase in the hydrogen ion concentration of the medium.

Rose and Miller¹² concur with the observations which suggest that test tube experiments give no true indication of the effectiveness of an antiseptic or germicide when applied to tissues or when mixed with blood, saliva and exudates. They studied certain mercurials in the presence of from 1 to 50 per cent blood solution with *Staphylococcus aureus* as the test organism and found that increase in blood concentration decreased antiseptic effectiveness by using the formula $C = Ke^{-mz}$, where C = concentration of blood (%), K = a constant for each antiseptic, e = base of naperian logarithms, m = coefficient of inactivation of the antiseptic and z = zone of inhibition of bacterial growth (mm.). It was concluded that the mercurials have no antiseptic action at certain critical blood levels. Hunt¹³ injected a strain of *Staphylococcus aureus* intravenously into mice and found that mercurial compounds failed to prevent infection or lessen necrosis if mixed with the bacterial suspension just before injection.

MODE OF ACTION

According to Brewer¹ the most generally accepted ideas regarding the manner in which the mercurials show antibacterial properties probably arise because mercury bichloride was known to coagulate the proteins by a direct combination with the tissues. It is now more or less believed that the mercurials precipitate bacterial protein. Modifications of this view, together with the surface absorption and enzyme destruction theories, have been reviewed by Brewer, but in conclusion he admits that not one of the suggested theories has offered a complete and satisfactory explanation.

7. Thaysen, A. C.: Some Observations on the Rideal-Walker Test, *J. Hyg.* 38: 558 (Sept.) 1938.

In 1917 Sollmann¹⁴ reported that it was difficult to kill bacteria on body surfaces because solutions which are definitely germicidal might destroy the tissues, and because chemical antiseptics are weakened by the presence of organic matter. If, however, it is possible to injure the bacteria in some manner, the injury may be enough to effect subsequent death of the bacteria either as a direct result of the cell injury or by aid of the tissue reactions.

Actual injury to the bacteria which have managed to get within the body tissues is even more difficult, since organic matter may be precipitated and hinder further any tissue penetration by the germicide that might conceivably occur.

COMPARATIVE VALUE

The efficiency of chemical disinfecting or germicidal agents is largely dependent on the form and material of objects to be sterilized. Attempted sterilization of utensils by chemical agents involves employment not only of solutions that are actually bactericidal but also of methods which ensure adequate contact between bacteria and solution. The latter is the more difficult part of the problem. Because the market is flooded with chemical agents which are as effective bacterially as or even better than a standard solution of phenol in ideal laboratory conditions, it does not necessarily follow that the same pathogenic organisms will be destroyed on instruments or skin which are protected by coatings of organic material whether it is dried mucus, coagulum or just grease and dirt.

Novak and Hall¹⁵ found an average of twelve staphylococci and diphtheroids per square centimeter on what was normally considered clean skin. Application of 50 per cent alcohol and 10 per cent acetone solution, a common solvent for antiseptics, destroyed 95 per cent of the bacteria on the skin. Only from 2 to 3 per cent more were killed when any commonly used skin antiseptic was added to this solvent. Tincture of green soap alone killed only 53 per cent of the skin bacteria. When skin antiseptics are desired, it is necessary to consider not only resident bacteria but also any transient bacteria that may be present. The same strains of an organism may show individual variation under different cultural environments.

Bass¹⁶ reviewed some of the previous literature and left open the suggestion that some of the antibacterial action attributed to the mercurials might be due to bacteriostasis. Using adult rabbits for experimentation with Birkhaug's method, which was reported in 1933, Bass tested a series of the more common agents. Using 70 per cent ethyl alcohol as a standard of comparison, which sterilized 27.7 per cent of skin areas treated, he found that sterilization of the skin by other agents ranged from 38 to 80 per cent. He found evidence that some of the newer organic preparations of mercury were of distinct value as antiseptics and possessed more germicidal activity than the older chlorides of mercury, but absolute sterilization was never obtained. Price¹⁷ has reported that 70 per cent by weight of ethyl alcohol is the most effective concentration of alcohol for antibacterial properties. Slight variations from this percentage lessens the bactericidal action. From his observations he evolved a simple technic for preoperative cleansing of the hands and arms. Essentially it consists of scrubbing the hands and arms with a brush, soap and warm water for seven minutes, drying them with a sterile towel, rinsing in 95 per cent alcohol to remove any remaining water, and then washing for three minutes in a basin well filled with 70 per cent alcohol (by weight). Later investigations by Price¹⁸ also revealed information on the germicidal values of mercury bichloride and of potassium mercuric iodide. When skin free of grease is washed in one of these mercurials there is formed a sterile impermeable "film" which protects the under-

lying cutaneous bacteria. This "film" is impervious to bacteria, slightly permeable to alcohol and very resistant to friction. However, beneath the "film" the bacteria are unharmed and multiply at a rapid rate. The formation of such a "film" probably explains why the older surgeons often enjoyed relative asepsis when operating without gloves. Price believes that mercury bichloride and potassium mercuric iodide (1:500) are of value in preoperative disinfection of the hands whenever an ungloved hand must be used in obstetrics or surgery. These agents may also have a place in the preparation of the field of operation but should not be depended on to effect sterilization at the site through which an incision is to be made.

Older forms of mercury, such as the bichloride, in addition to not killing spores on instruments, corrode the metal and may cause dermatitis when in prolonged contact with the skin. Because of their toxicity when injected parenterally, they could not be used in chemotherapy. About the close of the World War the first organic mercurials appeared with great claims for ability actually to sterilize instruments. However, these claims lacked support by way of adequate tests. Their inability to sterilize sutures was reported by Brewer,¹⁹ while making a survey for the Council on Pharmacy and Chemistry.

Examination by the Chemical Laboratory of the American Medical Association has revealed that decomposition with the liberation of free mercury of many organic mercurials occurs on standing. The preparations examined included solutions in ampules, lubricating jellies and creams. This work appears to indicate that the organic mercurials are not sufficiently stable to prevent partial disintegration from occurring over varying periods of time.

CONCLUSION

Mercurial preparations are used for antiseptic and disinfecting purposes, but they cannot be expected to destroy spores after several hours' exposure or even be relied on to destroy some nonsporulating bacteria. The organic compounds of mercury are claimed, in general, to be less irritating and less toxic than the older preparations of mercury, but their germicidal activity is in doubt in many instances, even though they may, and often do, have a highly bacteriostatic value. Because of their bacteriostatic ability the organic mercurials are of value as first aid prophylactic antiseptics and as preservatives of certain biologicals for parenteral use. Claims for their ability to penetrate deeply into living tissue and to act as chemotherapeutic agents have yet to be adequately supported.

Sterilization of contaminated instruments and dishes, whether by autoclaving, boiling water or live steam, is more simple, fairly rapid, inexpensive and more certain than by any chemical method known at the present time. Once the material is sterilized and kept dry in an airtight container, it will remain sterile for a considerable period.

It is thus apparent that the organic mercurials can be used for certain bacteriostatic purposes and in some instances for bactericidal effects. However, they cannot be expected to destroy pathogenic spores, and even their action on nonsporulating bacteria is limited. Skin sepsis is best prevented by a thorough cleansing with soap and water and a solvent such as alcohol and acetone before using any antiseptic agent. At present, ethyl alcohol (70 per cent by weight) appears to be one of the most reliable antibacterial agents.²⁰

No safe organic mercurial compound has yet been offered which will guarantee destruction of spores in suture material.

20. In practice, the amount of alcohol in a preparation is generally referred to in terms of per cent by volume. Certain regulations in pharmaceutical practice state that the per cent of alcohol always means "by volume," unless expressed in terms by weight. As ethyl alcohol U. S. P. varies somewhat in water content, generally from 94 to 95 per cent by volume, it is impossible to give a definite formula for preparing alcohol 70 per cent by weight. Probably the best method would be to add approximately 25 cc. of water to 100 cc. of alcohol and adjusting the mixture so that the specific gravity at a temperature of 25 °C. is 0.8658. A stock solution may be checked by determining the specific gravity. Alcoholometric tables appear in many books of analysis, and an official table appears in the U. S. P. XI. A Westphal balance, or a well graduated hydrometer, is satisfactory for determining specific gravity.

AMERICAN COLLEGE OF SURGEONS JOINS FORCES WITH AMERICAN MEDICAL ASSOCIATION IN HOSPITAL CENSUS

Each year the Council on Medical Education and Hospitals of the American Medical Association takes a census of registered hospitals, numbering more than 6,000. The American College of Surgeons also has obtained statistical reports from hospitals already meeting the minimum standards of the College and those under consideration for approval. The combination of these reports into one simplified form will be welcome to the hospitals and especially to their administrative officers. Printed in triplicate, a single typing of the form supplies a report for each of the interested organizations and provides a carbon copy for the files of the hospital. All forms are coded for punch card tabulation. Thus, with a minimum of trouble and expense, both the College and the Council secure such information as is necessary for the continuance of their recognition. Also the compiled returns serve as a basis for the Hospital Number of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, which places essential information in the hands of all hospitals, physicians and others concerned. This should render unnecessary many of the questionnaires now sent to hospitals.

It is gratifying to record that the returns are coming in more promptly than in other years and that over 50 per cent of them were received within ten working days after mailing. Hospitals that have not yet responded should do so at once. Staff physicians can do a good turn by asking at the office whether the report has been completed and mailed.

The hospitals approved for the training of interns and residents will receive their questionnaires late in December so that the reports may cover the calendar year 1940.

The combined census is one feature of the program for increased cooperation between the American Medi-

cal Association and the American College of Surgeons. Another phase of this get-together movement is the coordination of hospital inspection so as to avoid duplication and extend inspection service for hospitals.

WAR MEDICINE—A NEW PUBLICATION

Beginning in January, the American Medical Association will publish a new periodical: "WAR MEDICINE," as a part of its contribution to the preparedness program. The editorial board of the publication will be the Committee on Information of the Division of Medical Sciences of the National Research Council. This committee includes Dr. Morris Fishbein, Editor of *THE JOURNAL*, as chairman, and the following associate editors: Mr. J. R. Bloomfield and Drs. John F. Fulton, Richard M. Hewitt, Ira V. Hiscock, Sanford V. Larkey and Robert N. Nye. In order to have direct cooperation with the governmental services, the following representatives of the Army and Navy Medical Corps and the United States Public Health Service have been chosen to cooperate with this editorial board: Col. C. C. Hillman, Com. Charles S. Stephenson and Dr. R. R. Spencer.

The Division of Medical Sciences of the National Research Council has developed a number of scientific committees which are actively at work preparing reports of various phases of medical service under military conditions. These official documents will be available to the new periodical for prompt publication. Already reports on chemotherapy, the standardization of the treatment of pneumonia, numerous problems concerned with medicine in aviation, peripheral nerve injuries, wound treatment, gas gangrene and similar subjects are being made available.

The American Medical Association, through its Committee on Medical Preparedness, is concerning itself with all the questions of personnel for preparedness and for military service. The official reports of this committee will also appear in the new periodical as well as special considerations that are given to economic and social problems of the medical profession in relationship to the emergency. Of especial importance also are the reports of official committees of the American Medical Association, such as the Council on Medical Education and Hospitals, the Council on Industrial Health and similar groups which will also be concerned with these problems.

Finally, much material is being developed by the Coordinating Committee on Medicine and Health of the Council of National Defense and by many other governmental agencies which are considering the national nutrition, the provision of hospital services and similar questions closely related to preparedness and defense.

The new publication will appear as a bimonthly. The Board of Trustees of the American Medical Association

tion, which has authorized its publication; has established a price of \$5 annually for the subscription. The periodical should be useful not only to the government services, which have indicated their wish to subscribe to this periodical for their official departments, but also to libraries and to individual physicians.

THE INDUSTRIAL NURSE

Competent industrial health service depends on the availability of physicians adequately trained in industrial medicine, hygiene and traumatic surgery. Ordinarily, however, assistance is necessary from other properly qualified professional personnel. Industrial medical departments provide excellent opportunities to nurses with proper aptitude, good comprehension of public health nursing methods and a sure sense of their own professional limitations. A clinical and administrative assistant of this character will be of immense aid to any industrial physician in the performance of many routine functions which make up the bulk of industrial dispensary procedure. The system works admirably under whole-time industrial physicians or under part-time physicians who spend regular visiting hours at a plant. In the absence of direct medical supervision, written standing orders, properly posted in the plant medical unit, will do much to inhibit assumption of services which require expert medical attention. Unfortunately, many of the smaller plants which have found it possible to arrange for some form of nursing service fail to recognize the need for such supervision or consider themselves unable to support even part-time medical aid. A nurse working under such conditions acts under heavy professional and ethical handicaps. Some form of medical supervisory arrangement is necessary to provide nurses with technical advice. The physicians on call for first aid and compensation work may be most helpful, particularly if they have some insight into the actual working environment. Committees on industrial health now being formed in county medical societies will find the industrial nursing field a fertile one for helpful and cooperative activity, both in a direct advisory capacity and as coordinators of private and public medical services. Frequently, they may be called to correct unhealthful industrial situations which the nurse uncovers. Unified service of this kind is already contemplated, using the part-time services of public health or visiting nurses paid for by small industry on a fee basis calculated according to hours per week required.

These relationships are particularly pertinent in view of the speeding up and intensification of industry that is occurring as part of the preparedness program. Many more nurses will be needed than are now available. They can make a valuable contribution to industry by supplying first aid and nursing care to plant personnel, assisting the physician in health examinations, and helping the worker to secure correction of defects through

reference to the family physician or other properly designated medical agency. The nurse is concerned with sanitary conditions within the plant and may in many ways promote the health and safety of industrial workers. The nurse should participate in the work of health education in industry and encourage sanitary and hygienic precautions that will diminish absenteeism due to illness and accident.

New requirements for industrial health service will demand much more trained personnel than is now available. Schools of nursing should concern themselves at once with courses in industrial hygiene not only to undergraduate but to graduate students. Better education regarding industrial hazards, industrial relationships and the principles of health organization will encourage industrialists to extend their employment of good industrial nursing services. The need for higher standards is well recognized by leaders in the nursing profession, and plans are currently under discussion for additional improvement. Community of interest is so great that no opportunity should be lost by the medical profession to assist the industrial nurse, individually and collectively, to elevate her professional status.

PROPOSED ADDITIONS TO AND DELETIONS FROM THE NEXT UNITED STATES PHARMACOPEIA

The new Revision Committee of the U. S. Pharmacopeia has already begun to consider recommendations on scope. A number of important policies were adopted at the 1940 U. S. Pharmacopeial Convention which apparently will be reflected in the type of articles to be included or deleted from the next revision. Because of the importance of the Pharmacopeia to the practice of medicine, the U. S. P. Subcommittee on Scope has wisely prepared a preliminary statement of the suggested changes. Both physicians and pharmacists should consider the proposals, and discussions may well be presented in the pharmaceutical and medical press. The president of the Pharmacopeial Convention and the chairman of the Subcommittee on Scope have outlined the policy under which medicinal substances have been admitted to the Pharmacopeia:

The Subcommittee on Scope, which decides admissions and deletions for a new Pharmacopeia, is primarily responsible for the value and usefulness of the book to the medical profession. The fundamental medical and pharmaceutical objectives of the Pharmacopeia from the time it was established have been to include a selected list of the best known and most thoroughly tested medicines of each revision period and also suitable usage or dosage forms or preparations of these important basic medicines. It has always been the aim of those responsible for the Pharmacopeia that it should be so comprehensive as to meet every need of medical practice, insofar as there are efficient medicinal products and medical aids known and available.

This principle of Pharmacopeial admissions has been maintained and practiced since 1820 and was emphatically reaffirmed by the Subcommittee on Scope during the recent meeting of the Committee of Revision. When it is determined that a medicinal substance or preparation fails to meet the standard of therapeutic excellence or service required by the Revision

Committee or when a patent situation intervenes, such a substance, or preparation, is denied admission to the Pharmacopeia. This policy of the Pharmacopeia of the United States is the basic policy for all pharmacopeias of the world. Under it is included any substance or preparation used in medicine which in the opinion of its experts is worthy of Pharmacopeial recognition. Under this accepted policy, the Pharmacopeia has been able to develop and maintain a unique voluntary service to medicine, pharmacy and the public, a contribution recognized and accepted by the medical and associated professions, and the manufacturing drug industry, and adopted by state and federal legislation.

Fifty-five additional products have been recommended for inclusion in the new Pharmacopeia, a few simply as pharmaceutical necessities. In addition, thirty or more substances have been recommended for inclusion, but because of trademark or patent involvements the names have been withheld until the committee has opportunity to give them further study and to discuss the question of proprietorship with the owners of the trademarks and patents. Elsewhere in this issue (see page 2110) may be found a list of additions and also a list containing titles of the products which the committee recommends to be deleted. The recommendations of the committee show constructive effort. On some items there may be a difference of opinion, particularly whether or not the products are sufficiently established to be recognized in the Pharmacopeia for purposes of use by the general practitioner.

Nomenclature of these products will be dealt with by another committee, which has indicated that, wherever possible, established nonproprietary terms will be used. The titles in themselves, as they appear in the present list, do not imply that the respective names are to be considered as final.

THE PROBLEM OF PSITTACOSIS

Psittacosis is primarily a disease of so-called psittacine birds such as parrots and parakeets. The disease is transmissible to man, however, and is characterized by high fever associated with symptoms of an atypical pneumonia. Occasionally the disease can be transmitted from man to man, but the most common source of human infection is from parrots and parakeets which have been kept as household pets. No doubt many infected birds will be distributed as Christmas presents, and the hazard at this time demands a warning.

Meyer and his colleagues¹ at the Hooper Foundation in San Francisco have been persistent in their research on this disease. Much information on the nature of the virus which causes psittacosis is now available. On the basis of ultrafiltration measurements verified by photomicrographic studies it has been determined that the infective particle of psittacosis has

a minimum size of from 0.2 to 0.3 micron. Furthermore the infective agent of psittacosis has been shown to be the elementary body itself and not a separable substance or an invisible particle of the same size. The virus can be satisfactorily cultivated on the chorio-allantoic membrane of the developing egg. Agglutinins for the elementary bodies of psittacosis have been produced experimentally in guinea pigs, and control experiments have proved that the agglutination reaction resulting was not due to the presence of foreign protein or virus contamination. Indeed, the virus of psittacosis as represented by the elementary bodies acts in all respects as a small micro-organism requiring an intracellular habitat for multiplication and survival. The particular value of the serologic investigations, however, resides in the fact that they have led to the demonstration that complement fixation tests with coccoid antigens prepared from virulent mouse spleens or Rivers-Li tissue cultures of the virus are specific in nature and serve as invaluable aids in the early and late diagnosis of human psittacosis. Preliminary observations indicate that either convalescent serum or a highly potent goat serum which has been produced may shorten the course of the human disease. A specific test is therefore available and new potentials for treatment are in sight.

Psittacosis is widely distributed among birds in this country. In one shipment of 161 parrots, parrotlets and conures from South America, Meyer and Eddy examined 158 following the preceding death of 3 of the birds. Both the Panama parrots and the macaws presented gross lesions of psittacosis in the form of emaciation and large spleens and livers with healed necroses. In fact, of the whole group only 15 parrotlets and 1 Wagner parrot were proved free of the virus of psittacosis. Similar high incidence of infection was found in shipments from Colombia and Australia.

Such high percentages of infection of imported birds for house pets underline the danger of wide distribution of human disease, and some effective means of eliminating the diseased birds is of great importance. One method employed has been to introduce the rice bird into new shipments of psittacine birds. This bird has been found susceptible to the virus and is ideal in certain respects for experiments. This exposure method, however, requires an observation period of not less than two to three months and might fail to answer the pertinent questions relative to latent psittacosis in the imported birds. In later experiments from 5 to 10 cc. of blood (depending on the size of the parrot) was withdrawn from the superficial ulnar vein without difficulty, provided the birds had been properly anesthetized with ether. The concentrated tissue culture in Rivers-Li medium was used in the preparation of antigens, and complement fixation reactions were performed according to a somewhat complex technique. These complement fixation reactions could be interpreted as indicative of previous contact of the parrots

F., and Eddy, Bernice U.: Psittacosis in Importations of Psittacine Birds from the South American and Australian Continent, *J. Infect. Dis.* **65**: 234 (Nov.-Dec.) 1939; The Value of the Complement Fixation Test in the Diagnosis of Psittacosis, *ibid.* **65**: 225 (Nov.-Dec.) 1939.

with the psittacosis virus. There is little doubt, therefore, that the complement fixation test may prove valuable in detection of the presence of psittacosis in an importation and for separating the healthy from the recovered birds. Others² have confirmed the value of the test. The complement fixation test, besides its function in birds, has also proved its usefulness as a diagnostic aid in human psittacosis both early and late. Further laboratory investigations aimed at improvement and refinement of technics are indicated and the development of a more effective specific method of treating the disease in man. Most promising at present is the use of convalescent serum and goat serum.

THERAPEUTIC TRIALS WITH RADIO-ACTIVE PHOSPHORUS

Several radioactive substances with possibilities for medical application have been prepared with the use of the cyclotron. Up to now radioactive phosphorus has been tried therapeutically more than any other element. Phosphorus, artificially made radioactive, appears to be especially interesting because it is easily manufactured in the cyclotron, because its half-life is relatively long, 14.8 days, and because phosphorus is important in organic and inorganic metabolism generally. Its essential difference from natural inactive phosphorus, according to Lawrence and his co-workers,¹ resides in the fact that its nucleus contains an extra neutron and it emits beta rays (electrons) when administered in the form of sodium phosphate. Bone eventually would be expected to retain a larger percentage than any other tissue, and bone, with such a high phosphorus content, would get the greatest number of radioactive atoms per gram. From studies on leukemia in mice it was considered possible that the administration of large quantities of radiophosphorus would seem to offer a method of getting more or less selective radiation in this disease. With this basis, Lawrence and his colleagues carried out metabolic and clinical studies employing radiophosphorus in six cases of leukemia—one lymphatic, one monocytic and four myelogenous leukemia. Although the clinical results were doubtful, it appeared that decreases in the number of white blood cells occurred in a manner similar to that produced by roentgen irradiation when large doses of radiophosphorus were given to patients with leukemia.

A later report by Lawrence² describes five additional cases of chronic myelogenous or chronic lymphatic leukemia treated by the oral administration of radiophosphorus in the form of sodium phosphate with resultant responses similar to those usually following roentgen or radium therapy. Two additional cases of polycythe-

mia vera were also reported in which similar treatment resulted in a fall in the hemoglobin, red blood cell count and reticulocyte count without evident destruction of the red blood cells. The principal advantages of this treatment according to Lawrence are that it offers a means of giving the whole body radiation continuously over a period of two or more weeks in a single oral dose of sodium phosphate, and there are no irradiation reactions.

Warren's³ report on the treatment of leukemia by radioactive phosphorus—just published—involved the study of four cases of acute or subacute leukemia. Most of the radioactive phosphorus used in the treatment of these cases was obtained from the Harvard cyclotron and had a half-life of 14.5 days. The desired amount of radioactive phosphorus ranging from one to four millicurie equivalents was dissolved in 5 per cent dextrose and physiologic solution of sodium chloride prepared for intravenous use, sterilized and injected intravenously. The intravenous route of administration was adopted because of the disadvantage of the oral route in that the proportion absorbed by way of the gastrointestinal tract is variable, and frequently over 10 per cent may fail to be absorbed. Two patients showed no significant response beyond minor changes in white cell count, and both subsequently died. In the two others some clinical improvement was noted, as evidenced by the general condition, level of white cell count and condition of bone marrow.

As yet the use of radioactive phosphorus as a therapeutic method is in the preliminary stage: the results offer promise, but important factors remain to be elucidated, including the type and stage of leukemia which might be expected to respond and the dosage and route of administration, both of which are still on a purely arbitrary basis. No doubt further investigation will clarify these points so that radiophosphorus or some other radioactive element can become firmly established as an addition to therapeutic methods.

Current Comment

THE CLEVELAND SESSION

Already the Council on Scientific Assembly has met, local committees are being established, places of meeting have been organized and movement has begun toward the making of a successful session for the American Medical Association in Cleveland, June 2-6, 1941. Elsewhere in this issue appears a table listing the hotels in Cleveland, with the prices that have been established for various types of hotel accommodations. Recent sessions of the American Medical Association have been attended by many thousands of physicians; in fact more than 12,000 registered at the meeting in New York last year. Obviously, it is desirable for every physician who plans to attend the Cleveland ses-

3. Warren, Shields: The Treatment of Leukemia by Radioactive Phosphorus, *New England J. Med.* 223: 751 (Nov. 7) 1940.

sion to reserve space as soon as possible. The Hotel Committee in Cleveland is convinced that it will be able to accommodate satisfactorily all physicians who wish to attend, provided some inkling may be obtained soon of the number of physicians who will attend and the type of accommodations which they will require. The cooperation of the medical profession in this matter will insure a greater degree of comfort, a more successful convention and more general satisfaction than can be

secured in any other way. If you plan to go to Cleveland, write at once to Dr. Edward F. Kieger, Chairman of the Hotel Committee, Cleveland Convention & Visitors' Bureau, Inc., 1604 Terminal Tower, Cleveland, Ohio, using preferably the blank which appears on advertising page 36 in this issue. Indicate a first, second and third choice of hotel. Indicate whether or not you will require extra space for your wife, your children or any other guests who plan to accompany you.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

COUNCIL OF NATIONAL DEFENSE

Coordination of Health, Welfare and Related Defense Activities

Pursuant to the authority vested in it by section 2 of the Act of Aug. 29, 1916 (39 Stat. 649), the Council of National Defense, with the approval of the President, hereby designates the Federal Security Administrator as Coordinator of all health, medical, welfare, nutrition, recreation and other related fields of activity affecting the national defense. In the performance of this responsibility the Federal Security Administrator as Coordinator shall, in cooperation with the Advisory Commission to the Council of National Defense, formulate and execute plans, policies and programs designed to assure the provision of adequate services of this character to the nation during the national defense emergency; and to that end he shall coordinate the facilities of existing federal agencies with respect to these several fields of action and shall establish and maintain liaison with such other agencies, public or private, as he may deem necessary or desirable.

The Federal Security Administrator is authorized, with the approval of the President, to appoint such advisory committees and subcommittees with respect to health, medical, welfare, nutrition, recreation and related activities as he may find necessary or desirable to assist him in the performance of his coordinating duties. Such committees and subcommittees may include representatives from federal departments and agencies, state and local governments, organized private groups and the public at large. The members of advisory committees and subcommittees shall serve as such without compensation but shall be entitled to actual and necessary transportation, subsistence and other expenses incidental to the performance of their duties. Each committee and subcommittee shall operate under the direction and supervision of the Federal Security Administrator as Coordinator and shall serve at his pleasure.

The Health and Medical Committee established by order of the Council of National Defense, dated Sept. 19, 1940, is hereby transferred to the Federal Security Agency, and such committee shall hereafter exercise its duties and functions under the direction and supervision of the Federal Security Administrator. Vacan-

cies occurring in the membership of this committee shall hereafter be filled by appointment of the Federal Security Administrator, with the approval of the President. All rules and regulations, projects and activities of the committee required to be approved by the Council of National Defense or the President shall, prior to submission thereto, be approved by the Federal Security Administrator.

Within the limits of appropriations allocated for purposes encompassed by this order, the Federal Security Administrator may contract with and transfer funds to existing governmental agencies and institutions and may enter into contracts and agreements with individuals or educational or scientific institutions for studies, reports, experimental investigations and expert counsel.

GENERAL CONFERENCE ON PSYCHIATRIC EXAMINATIONS

The Director of Selective Service, C. A. Dykstra, invited a number of leading specialists in the treatment of mental disorders to Washington, D. C., December 5, for a general conference on the standardization of psychiatric examinations of Selective Service trainees. On the program of the conference was a proposal to hold a series of conferences throughout the United States which would serve as "refresher" courses for the local board physicians who examine Selective Service registrants when they are called up for physical examination. Mr. Dykstra believes that if local board examining physicians and the specialists attached to medical advisory boards are given an opportunity to attend seminars on the subject it will tend to bring about a desired uniformity in the psychiatric examinations. Those who were invited to attend the conference in Washington, December 5, included Dr. Winfred Overholser, U. S. P. H. S., St. Elizabeth Hospital, Washington, D. C.;

Lieut. Col. William C. Porter, U. S. Army, Walter Reed Hospital, Washington, D. C.; Capt. Dallas G. Sutton, U. S. Navy, Naval Hospital, Washington D. C.; Dr. Howard W. Potter, Bellevue Hospital, New York; Dr. Harry A. Steckel, American Psychiatric Association, Syracuse, N. Y.; Dr. Martin J. Cooley, Veterans Administration, Washington, D. C.; Mr. Frederic Osborne, chief of Civilian Advisory Committee on Selective Service; Dr. Roscoe W. Hall, St. Elizabeth Hospital, Washington, D. C.; Dr. Harry Stack Sullivan, White Psychiatric Foundation, New York; Dr. Wendell S. Muncie, Johns Hopkins Hospital, Baltimore; Dr. Rose Chapman, Sheppard and Enoch Pratt Hospital, Towson, Md., and Lieut. Col. Charles B. Spruit, General Headquarters, Army War College.

STUDY OF AIRPLANE PILOTS

The assistant secretary of commerce, Robert H. Hinckley, has announced the completion of arrangements by which the Mayo Foundation will conduct extensive research into the correlation between physical examinations of civilian airplane pilots and their actual performance in flight. The Mayo Foundation will conduct this research as a public service and at its own expense, the only cost to the government being flight courses for several of the doctors conducting these studies. The aim will be to develop more accurate yardsticks to predict on the ground the relative ability of pilots and prospective pilots. Ten Mayo Foundation specialists in various fields who studied the student pilots on the ground followed them step by step through the flight courses. Several of the Mayo physicians are already flight surgeons and others will take the civilian pilot training courses along with the students who are studying.

CALIFORNIANS SEND SUPPLIES TO BRITISH RED CROSS

The Medical Committee of the British War Relief Association of Northern California has purchased several ambulances and mobile canteens and sent them to the British Red Cross; the committee has been sending also other medical and surgical supplies. A plan is under way now to purchase a desivac machine of 5 liters capacity, which prepares powdered blood plasma in which are all of the original vital blood elements except the erythrocytes and water. Powdered plasma will be sent to the British Red Cross, where the only preparation necessary to make it instantly available for intravenous transfusion will be the addition of sterile distilled water. Desivac machines for yielding powdered plasma are already in use in a few of the military hospitals in England. The committee considers that this machine will be a link also in the medical preparedness program of the United States if powdered plasma becomes necessary for our own military forces; it will also make powdered plasma available to public health departments in the San Francisco Bay area in case of a major industrial disaster.

The unit will be installed if feasible in a San Francisco teaching hospital and all its operations will be under direct supervision of doctors who have volunteered their services.

The machine will be purchased with donations; any one desiring to contribute for this purpose may send donations to the B. W. R. A., Northern California Plasma Fund, 100 Bush Street, San Francisco.

MEDICAL AND SURGICAL SUPPLY COMMITTEE

Nearly \$100,000 has been received by the Medical and Surgical Supply Committee of America, 420 Lexington Avenue, New York, in cash and medical supplies and equipment for shipment to emergency hospitals in England. The cash is converted into medical supplies. Among the contributors have been individuals and hospitals in various states and pharmaceutical houses, one of which contributed 1,000,000 vitamin capsules and tablets. The Anglo-American Committee for War Refugees cabled the committee requesting hot water bottles and rubber sheeting, and in response 500 hot water bottles and 1,000 yards of rubber sheeting are being shipped. The committee hopes to send a total of 1,000 first aid outfits and an equal number of operating sets to England before Christmas to help equip air raid shelters, first aid posts and auxiliary hospitals. According to Mrs. Ronald B. Balcom, executive chairman, the administrative expenses of the committee remain at less than 4.5 per cent of the contributions. New names on the National Committee are Drs. Chester D. Allen, William D. Anderson, Daniel H. Anthony, Julian B. Blue, Kinsey M. Buck, Edward G. Campbell, Willis C. Campbell, Arthur F. Cooper, Jewell M. Dorris, all of Memphis, Tenn.; Dr. Claude B. Squires of Charlotte, N. C., and Dr. Julian Deryl Hart of Durham, N. C., Dr. Thomas H. Cheavens of Dallas, Texas, and Dr. Joel J. Pressman of Los Angeles.

COMMITTEE ON NURSING APPOINTED

The Health and Medical Committee of the Council of National Defense announced membership of a subcommittee on nursing, of which Miss Mary Beard, director of nursing, American Red Cross, has been named chairman. Members are Miss Marion Howell, dean of the Frances Payne Bolton School of Nursing, Western Reserve University, Cleveland; Miss Nellie Hawkinson, professor of nursing education, University of Chicago; Sister M. Olivia, dean of the School of Nursing, Catholic University of America, Washington, D. C., and Miss Julia Stimson, chairman of nursing, Council of National Defense, and president of the American Nurses' Association, New York. Functions of the subcommittee on nursing are to conduct investigations and studies of the nursing needs of the nation and make recommendations for coordinating nursing requirements of the country as a whole with those for national defense.

NEW MILITARY HOSPITAL IN SANTA BARBARA

Plans have been announced for a new hospital in Santa Barbara, Calif., to cost approximately \$1,042,800 and with a capacity of 750 beds to be built in accordance with war department policy governing provision of such establishments for new stations. Full facilities will be provided for competent operation and administration and include such buildings as surgical, medical and isolation ward buildings, dental and eye, ear, nose and throat clinics, an infirmary for sick call and first aid, a complete laboratory, physical therapy building, administration and surgery buildings, mess halls, quarters for bachelor officers, for nurses and for other medical personnel, recreation buildings, post exchange, workshops and storage buildings, and buildings for the fire protection service. It is expected that the hospital will be ready for occupancy early in 1941.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

WAR DEPARTMENT

The following additional medical reserve corps officers had been ordered to extended active duty with the regular army by direction of the War Department, Washington, D. C., up to November 29:

CAMPBELL, Clayton C., Jr., 1st Lieut., Long Beach, Calif.
CAMPBELL, Paul Andrew, Captain, Chicago.
COOPER, Arlin Bernice, 1st Lieut., Ben Wheeler, Texas.
ESTES, Woodrow B., 1st Lieut., Miami, Fla.

EVANS, Wesley Mort, 1st Lieut., Munhall, Pa.
HEWLETT, Frank Wilson, 1st Lieut., Coral Gables, Fla.
HOLSCHER, Edward Charles, 1st Lieut., Kirkwood, Mo.
JAASTAD, Leonard Binning, 1st Lieut., Milwaukee.
LIPIN, Raymond Joseph, 1st Lieut., Pasadena, Md.
NOVAK, John Goodman, 1st Lieut., Pittsburgh.
RININGER, Harold Casper, Rockport, Ind.
SAWYER, Lester Jacob, 1st Lieut., San Francisco.
SHEAR, Manuel Heine, 1st Lieut., Austin, Texas.
WITTELS, Theodore S., 1st Lieut., Newton, Texas.

SECOND CORPS AREA

The following additional medical reserve corps officers had been ordered to active duty by the Commanding General, Second Corps Area, up to November 29. The Second Corps Area comprises the states of New York, New Jersey and Delaware.

AYER, Guy D., Jr., 1st Lieut., Cooperstown, N. Y.
BASTON, Frank K., 1st Lieut., Tulley, N. Y., 1st Military Area.
BLAUVELT, Willard J., 1st Lieut., Port Byron, N. Y., 1st Military Area.
BLEICHFELD, Samuel, Captain, 119 Highland Avenue, Buffalo, New York, 1st Military Area.
CALEF, Victor C., 1st Lieut., New York.
CARPENTER, Robert B., Captain, Buffalo.
DODGE, Lynn, Major, Fairport, N. Y.

FISHBEIN, Elliot, 1st Lieut., Paterson, N. J.
FREEMAN, Ray McArthur, Captain, Linden, N. J.
GERSHMAN, Maurice, 1st Lieut., Brooklyn, 2d Military Area.
HERO, Bryon A., 1st Lieut., Long Island City, N. Y., 2d Military Area.
KASICH, Milosh, Major, New York.
MARSH, Edward H., Major, 7 Leith Place, White Plains, New York, 2d Military Area.
MAXWELL, Cyrus H., Captain, Albany, N. Y.
MENDELSON, Michael, 1st Lieut., Binghamton, N. Y.
MORAN, John F., Jr., 1st Lieut., Lambertville, N. J.
PASCAL, Vincenzo, Lieut. Col., New York.
RAINEY, Harry G., 1st Lieut., Ogdensburg, N. Y., 1st Military Area.
RAPPOPORT, Milton, 1st Lieut., Brooklyn, 2d Military Area.
SMITH, Percy L., 1st Lieut., Dayton, N. J.
STANSBURY, Frederick C., 1st Lieut., Syracuse, N. Y.
WAUGH, David D., 1st Lieut., Brooklyn, 2d Military Area.
WINTER, Carl M., 1st Lieut., Camden, N. J., 3d Military Area.

THIRD CORPS AREA

Following is a list of additional medical reserve corps officers who up to November 29 had been ordered to extended active duty by Third Corps Area order. The Third Corps Area comprises the states of Pennsylvania, Virginia, District of Columbia and Maryland.

ABRAMOVITZ, Leonard Jerome, 1st Lieut., Baltimore.
BANKERT, Charles William, 1st Lieut., Linesville, Pa.
BASTACKY, Morris, 1st Lieut., Pittsburgh.
BIDUS, Leo Marion, 1st Lieut., Philadelphia.
BISHOP, William Russell, Captain, Flint Hill, Va.
BLUMBERG, Leon David, 1st Lieut., Philadelphia.
CARP, Albert Alexander, 1st Lieut., Philadelphia.
CHERKASKY, Martin, 1st Lieut., Philadelphia.
DEWOODY, Gerald McDowell, Captain, Center, Pa.
DROZD, Joseph, 1st Lieut., Baltimore.
ENGELMAN, Frank Ephraim, Captain, Pittsburgh.

GAEV, Samuel David, Captain, Philadelphia.
GRIFFITHS, John Owen, 1st Lieut., Philadelphia.
HABER, Richard Edward, 1st Lieut., Pittsburgh.
JOHNSON, William Arthur, 1st Lieut., Uniontown, Pa.
KRAUSZ, Martin Richard, 1st Lieut., Philadelphia.
LAWRY, Lee Llewellyn, Jr., 1st Lieut., Philadelphia.
LICHTENSTEIN, George Maurice, 1st Lieut., Philadelphia.
MERLIN, Albert Abraham, 1st Lieut., Philadelphia.
MICHAELSON, Ernest, 1st Lieut., Bladensburg, Md.
SACHS, Fred, 1st Lieut., Bloomsburg, Pa.
SCHWAB, John Edward, 1st Lieut., Philadelphia.
SISSON, Harold Edward, 1st Lieut., Haynesville, Va.
STANLEY, Thomas Zborowski, 1st Lieut., Wilkes-Barre, Pa.
STEINMETZ, Henry Gottlieb, Captain, Arlington, Va.
STRATTON, James David, 1st Lieut., Brackenridge, Pa.
VIOLETTI, Raffaele Lombardo, 1st Lieut., Philadelphia.
VOLKIN, Leonard Bernard, 1st Lieut., Ernest, Pa.
WARREN, Charles Weston, 1st Lieut., Upperville, Va.
WOODHOUSE, Samuel Lawrence, Jr., Captain, Philadelphia.

FOURTH CORPS AREA

The following additional medical reserve officers have been ordered to active duty by Fourth Corps Area Order since November 22. The Fourth Corps Area comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana.

BELL, John A., Jr., 1st Lieut., Dublin, Ga.
BOWDEN, Ralph O., 1st Lieut., Savannah, Ga.
BRANDON, Robert W., Jr., 1st Lieut., Martin, Tenn.
BUMGARNER, John R., 1st Lieut., Wilkesboro, N. C.
CALDWELL, Gene D., 1st Lieut., Shreveport, La.
CATHELL, Edwin J., 1st Lieut., Lexington, N. C.
CHERRY, James H., 1st Lieut., Asheville, N. C.
CHEW, Nathaniel J., 1st Lieut., Bristol, Tenn.
CROOM, Robert D., Jr., Captain, 1st Lieut., Maxton, N. C.
CROW, Robert H., 1st Lieut., Cowpens, S. C.
DOWMAN, Charles E., 1st Lieut., Atlanta, Ga.
ELDRIDGE, Franklin G., Captain, Valdosta, Ga.
EVANS, Milton L., 1st Lieut., Memphis, Tenn.
FAILLA, Anthony, 1st Lieut., Pineville, La.
FERRELL, Thomas J., 1st Lieut., Waycross, Ga.
FINGER, Elliott, Captain, Marion, S. C.
FREEMAN, James V., 1st Lieut., Jacksonville, Fla.
GALIN, Albert N., 1st Lieut., Brunswick, Ga.
GOLSON, Willard R., Captain, Macon, Ga.
HAMILTON, Alfred T., 1st Lieut., Chapel Hill, N. C.
HAMMOND, Alfred F., Jr., 1st Lieut., Grifton, N. C.
HARPER, Sage, 1st Lieut., Wray, Ga.
HART, Oliver J., Captain, Winston-Salem, N. C.
HENSON, George C., Captain, Knoxville, Tenn.
HOCHFELDER, Bernard, 1st Lieut., New Orleans.
HOLDER, Franklin P., 1st Lieut., Eastman, Ga.
HOUSER, Frank M., 1st Lieut., Macon, Ga.
HUFSTEDLER, Fred E., 1st Lieut., Lenoir City, Tenn.

HUTCHINS, James D., 1st Lieut., Crystal Springs, Miss.
HYER, Yeaden M., 1st Lieut., Chester, S. C.
JONES, Lewis M., 1st Lieut., Opelika, Ala.
KENDALL, Cyrus E., 1st Lieut., Madison College, Tenn.
LESHNER, John H., 1st Lieut., Knoxville, Tenn.
LEWIS, Walter G., 1st Lieut., Stokesdale, N. C.
LYLES, Robin, 1st Lieut., Columbia, Tenn.
MACLENNAN, Edward R., 1st Lieut., Opp, Ala.
MANLEY, David B., 1st Lieut., Holopaw, Fla.
MILLER, James B., 1st Lieut., Columbia, Tenn.
MORROGH, Lailor A., Jr., 1st Lieut., Breaux Bridge, La.
NEVANS, Herman, 1st Lieut., Livingston, Tenn.
PERKINS, George E., 1st Lieut., Lake Worth, Fla.
POMERANCE, Joseph B., Captain, Miami Beach, Fla.
RAINEY, William T., Captain, Tiptonville, Tenn.
SAPPINGTON, Thomas A., 1st Lieut., Thomaston, Ga.
SINCLAIR, Robey T., Jr., 1st Lieut., Whiteville, N. C.
SLIPAKOFF, Leon, 1st Lieut., New Iberia, La.
SLOAN, William S., 1st Lieut., Wilson, N. C.
SMITH, Daniel L., Jr., 1st Lieut., Spartanburg, S. C.
SORRELLS, John E., 1st Lieut., Iowa, La.
STAPLETON, John L., 1st Lieut., Columbus, Ga.
TAYLOR, Harlan H., 1st Lieut., Cookeville, Tenn.
TIMMONS, Thaddeus A., 1st Lieut., Pamlico, S. C.
WALSH, John K., 1st Lieut., Florence, S. C.
WATT, Edward C., Jacksonville, Fla.
WHITFIELD, Robert L., Jr., Captain, Jamestown, Tenn.
WORK, Samuel D., Jr., 1st Lieut., Forsyth, Ga.
YOUNG, Henry D., Jr., 1st Lieut., Bushnell, Fla.

Orders Revoked

Orders have been revoked on the following named officers reported on a previous report:

ARP, Charles R., 1st Lieut., Atlanta, Ga.
BRABHAM, Vance W., Jr., 1st Lieut., Augusta, Ga.
HARRELL, Henry L., Captain, Ocala, Fla.

FIFTH CORPS AREA

The following additional medical reserve corps officers had been ordered by Fifth Corps Area Order to active duty up to November 22. The Fifth Corps Area comprises the states of Ohio, West Virginia, Indiana and Kentucky.

AIR, Clements W., 1st Lieut., Ludlow, Ky.
BATEMAN, Robert G., 1st Lieut., Richmond, Ky.
BLOUNT, Rankin C., 1st Lieut., Lexington, Ky.
BROSHEER, John R., 1st Lieut., Middlesboro, Ky.

COHEN, Robert, Captain, Louisville, Ky.
DITTMER, Jack E., 1st Lieut., Valparaiso, Ind.
FLAN, Moses, 1st Lieut., Paintsville, Ky.
HOLTZCLAW, Morris Richard, 1st Lieut., Somerset, Ky.
LOONEY, John E., 1st Lieut., Praise, Ky.
MCALLISTER, Max F., 1st Lieut., Outwood, Ky.
MCCOLLUM, Wendell D., 1st Lieut., Beattyville, Ky.
NOE, Joseph T., 1st Lieut., Wheelright, Ky.
PORTER, Robert F., 1st Lieut., Middlesboro, Ky.
STERNBERG, Elmer G., 1st Lieut., Cincinnati.
STINE, Frederick, 1st Lieut., Fort Thomas, Ky.

EIGHTH CORPS AREA

The following additional medical reserve officers had been ordered to active duty by Eighth Corps Area order up to December 6. The Eighth Corps Area comprises the states of Colorado, Arizona, New Mexico, Oklahoma and Texas.

AHERN, William Thomas Aloysius, 1st Lieut., Mesa Verde, Colo.
ALBI, Roger Vincent, 1st Lieut., Denver.
ANGUS, Howard, 1st Lieut., Lawton, Okla.
AUSTIN, Dale J., 1st Lieut., Dallas, Texas.
BERK, Ira Jay, Captain, McAllen, Texas.
BEST, Ralph L., 1st Lieut., Skiatook, Okla.
BLOSS, Claude M., 1st Lieut., Okemah, Okla.
BRALLIAR, John Seward, 1st Lieut., Wickenburg, Ariz.
BURNETT, Thomas Raynes, Major, Mission, Texas.
CARLOCK, John Hoyle, Jr., 1st Lieut., Ardmore, Okla.
CLARK, John Vincent, 1st Lieut., Oklahoma City.
CUNNINGHAM, Charles Donald, 1st Lieut., Seminole, Okla.
DIMOND, Edgar A., 1st Lieut., Muskogee, Okla.
EVANS, Robert Erle, 1st Lieut., Ada, Okla.
EWELL, William C., 1st Lieut., Tulsa, Okla.
FRY, Francis P., Jr., 1st Lieut., Frederick, Okla.
GALLAGHER, C. A., 1st Lieut., Oklahoma City.
GOOCH, James Oliver, 1st Lieut., Shamrock, Texas.
GRANT, Richard B., Jr., Captain, Bryan, Texas.
HANDLEY, James Jefferson, Major, Greenville, Texas.
HARTGRAVES, Thomas Anderson, Major, Phoenix, Ariz.
HAWKER, Laverne Joseph, 1st Lieut., Fort Worth, Texas.
HOLMES, Raynor E., Jr., 1st Lieut., Canon City, Colo.
HOPPER, John Jackson, 1st Lieut., Stanton, Texas.
HUGGINS, James Richard, 1st Lieut., Oklahoma City.
JORDAN, Robbie C., 1st Lieut., Austin, Texas.
KELLAM, Seth White, 1st Lieut., Menard, Texas.
KERNEK, Clyde, 1st Lieut., Holdenville, Okla.
KERNEK, Paul, 1st Lieut., Oklahoma City.
KUYKENDALL, Fred D., 1st Lieut., Eaton, Colo.
LEIGHT, Sidney B., 1st Lieut., Denver.
LEEMEE, Raymond Adolphe, 1st Lieut., Odessa, Texas.
LERNER, Ben Leonard, 1st Lieut., Houston, Texas.
LIVINGSTON, Lawrence G., Captain, Cordell, Okla.
McFARLING, James Everett, 1st Lieut., Humble, Texas.

MARTIN, Howard C., 1st Lieut., Oklahoma City.
MINOWITZ, David Louis, 1st Lieut., Fairplay, Colo.
NICKS, Frank Irvin, 1st Lieut., Manitou Springs, Colo.
O'NEILL, Francis Edward, 1st Lieut., Sanderson, Texas.
PEACOCK, George Eugene, 1st Lieut., Jacksonville, Texas.
PHILLIPS, Oliver Mack, 1st Lieut., Fort Worth, Texas.
PICKETT, Britton E., Jr., 1st Lieut., Carrizo Springs, Texas.
PIERSON, Marcus A., 1st Lieut., Galveston, Texas.
RAFTER, John Ralph, 1st Lieut., Muskogee, Okla.
RECORDS, John Williams, 1st Lieut., Oklahoma City.
ROARK, Frank Earl, 1st Lieut., Monticello, Utah.
SANGER, Paul G., 1st Lieut., Vinita, Okla.
SCHUESSLER, Willard W., Captain, Dallas, Texas.
SEYLER, Louis Walter, 1st Lieut., Commerce, Texas.
SIEVER, James Monroe, 1st Lieut., Dallas, Texas.
SIMON, John Franklin, 1st Lieut., Alva, Okla.
STUBBS, James B., 1st Lieut., Sweetwater, Texas.
STUMP, Robert M., Captain, Phoenix, Ariz.
SWANSON, Howard Edward, 1st Lieut., Denver.
SWEARINGEN, Robert Goodwin, Captain, Corpus Christi, Texas.
SWINNY, Boen, Major, San Antonio, Texas.
SWITZER, Fred D., 1st Lieut., Hugo, Okla.
TUBBS, William M., 1st Lieut., Silver City, N. M.
TURNBOW, William Ray, 1st Lieut., Tulsa, Okla.
VAUGHAN, Luther Matthews, 1st Lieut., Houston, Texas.
WAGNER, Gerald W., 1st Lieut., McKinney, Texas.
WILKERSON, John M., 1st Lieut., Checotah, Okla.
WILSON, Jewell R., 1st Lieut., Seminole, Okla.
ZEDLER, Garland Gus, 1st Lieut., Austin, Texas.
ZEHNPFENNIG, Urban H., 1st Lieut., Merkel, Texas.

Orders Revoked

The recent Eighth Corps Area headquarters order assigning the following medical reserve corps officers to active duty have been revoked:

COOPER, Elmer E., 1st Lieut., Nogales, Ariz.
MARTIN, Howard C., 1st Lieut., Oklahoma City.
ROARK, Frank Earl, 1st Lieut., Monticello, Utah.
STOUGH, Austin R., 1st Lieut., McAlester, Okla.
WALLACE, Gordon K., Captain, Dallas, Texas.

NAVAL RESERVE OFFICERS ORDERED TO ACTIVE DUTY

The following additional naval reserve officers have been ordered to active duty:

ASHTON, Wilbur L., Lieut. Comdr., M. C.-V. (S), Umatillo, Fla., Naval Air Station, Jacksonville, Fla.
BENJAMIN, Emanuel W., Lieut. Comdr., M. C.-V. (S), Providence, R. I., Naval Hospital, Newport, R. I.
BOLES, Albert, Lieut. Comdr., M. C.-O., Oakland, Calif., Naval Air Station, Alameda, Calif.
CARTER, Curtis H., Lieut. (j. g.) M. C.-V. (G), Augusta, Ga., Naval Hospital, Pensacola, Fla.
CHAMBERLAIN, John W., Lieut. (j. g.) M. C.-O., Belmont, Mass., Naval Reserve Aviation Base, Squantum, Mass.
FRANCE, Richard, Lieut., M. C.-V. (S), Baltimore, Naval Hospital, Philadelphia.
GEIBEL, Frank B. C., Lieut., M. C.-V. (S), Washington, D. C., Naval Hospital, Philadelphia.
GROVE, Pembroke, T., Lieut. (j. g.) M. C.-V. (S), Washington, D. C., Naval Hospital, San Diego, Calif.
HALBACH, Robert M., Lieut. Comdr., M. C.-V. (S), Jamestown, R. I., Naval Hospital, Newport, R. I.
HANSON, Frederick C., Lieut., M. C.-V. (S), Providence, R. I., Naval Torpedo Station, Newport, R. I.
HORWITZ, Ellis Rerry, Lieut. Comdr., M. C.-V. (S), Philadelphia, Naval Hospital, Philadelphia.
HUBER, Paul R., Lieut. Comdr., M. C.-O., Chicago, Ninth Naval District Headquarters, Great Lakes, Ill.
HUGHES, William N., Lieut. Comdr., M. C.-V. (S), Providence, R. I., Naval Hospital, Newport, R. I.
IVORY, Harry S., Lieut. Comdr., M. C.-V. (S), Point Pleasant, N. J., Naval Air Station, Lakehurst, N. J.

KEARNS, Jerry J., Lieut. Comdr., M. C.-V. (S), Chicago, Naval Training Station, Great Lakes, Ill.
LLOYD, Allen S., Lieut., M. C.-V. (S), Los Angeles, Norfolk Naval Hospital, Portsmouth, Va.
LUPTON, Charles H., Lieut. Comdr., M. C.-V. (S), Norfolk, Va., Norfolk Naval Hospital, Portsmouth, Va.
MACALUSO, Anthony, Lieut. Comdr., M. C.-O., Newton, Mass., Naval Reserve Aviation Base, Squantum, Mass.
NORTHINGTON, Page O., Comdr., M. C.-O., New York, Third Naval District Headquarters, New York.
O'CONNOR, Harry A. D., Lieut. Comdr., M. C.-V. (S), New York, Naval Hospital, Brooklyn.
PAGE, Henry F., Lieut. (j. g.) M. C.-V. (S), Philadelphia, Naval Hospital, Philadelphia.
SCARNEY, Herman D., Lieut., M. C.-O., Detroit, Naval Reserve Aviation Base, Detroit (Grosse Ile), Mich.
SCHMIDHOFFER, Ernst, Lieut. (j. g.) M. C.-V. (S), Boston, Naval Hospital, Chelsea, Mass.
SCHNEIDER, Herbert H., Lieut. (j. g.) M. C.-V. (G), Rochester, Minn., Naval Hospital, Pensacola, Fla.
SCHWAB, William John, Lieut. (j. g.) M. C.-V. (G), Providence, R. I., Naval Torpedo Station, Newport, R. I.
SMART, Frank P., Lieut. Comdr., M. C.-V. (S), Norfolk, Va., Norfolk Naval Hospital, Portsmouth, Va.
STEINMUELLER, Karl J., Lieut. Comdr., M. C.-V. (S), Baltimore, Naval Hospital, Annapolis, Md.
TURNER, Howard K., Lieut. Comdr., M. C.-V. (S), Providence, R. I., Naval Hospital, Newport, R. I.
WEAVER, Harry S., Jr., Lieut., M. C.-O., Philadelphia, Fourth Naval District Headquarters, Philadelphia.
WITTON, Cecil L., Lieut., M. C.-V. (S), Central Islip, N. Y., Naval Training Station, Newport, R. I.

ORGANIZATION SECTION

ASSOCIATED HEALTH FOUNDATION, INC.

The Associated Health Foundation, Inc., with offices at 57 West Fifty-Seventh Street, New York, has received a license from the State Department of Insurance as provided under the recent amendment to the New York state insurance laws and has been approved by the State Department of Social Welfare. The foundation is not directly connected with or controlled by either the Medical Society of the State of New York or any county medical society. It is a nonprofit, medical expense indemnity plan organized in accordance with the law referred to. It is managed by a nonsalaried board of trustees made up of fifteen physicians and ten laymen. Medical matters are handled by a medical board composed of eight physicians. Any physician licensed in the state of New York is eligible to become a participating member of the plan. Members are permitted free choice of any physician who agrees to the terms of the plan.

The plan is designed to provide adequate medical care for persons below the "comfort level." Annual income limits are from \$1,800 for a single person to \$3,000 for a family with two or more children. Subscribers' dues are \$18 a year for a single person, \$30 a year for husband and wife, \$12 a year for a dependent child between 16 and 18 years old and \$7.50 for a dependent child under 16 years of age. For this the subscriber receives "complete medical and surgical care, including x-ray and laboratory tests from the underwriting physicians." The following classes of cases are excluded: workmen's compensation, elective surgery during the first eleven months, obstetric care during the first ten months, drug addiction, chronic alcoholic conditions, venereal diseases and nervous and

mental diseases. Services are also not given to any one who "prior to or at the time of their application for membership" have had any one of the following diseases: insanity, pernicious anemia, cancer, diabetes, psoriasis or any incurable skin disease, tuberculosis, chronic nephritis, osteomyelitis or chronic heart disease, or for any disease or condition existing at the time of the subscriber's application, venereal diseases during the first ten months, and plastic or cosmetic surgery.

The incomes from subscribers are to be divided as follows: 20 per cent for administration, and of the remaining 80 per cent "60 per cent thereof is used to pay general practitioners on a capitation basis and the remaining 40 per cent to pay specialists, consultants, surgeons, x-ray and laboratory men on a unit basis using the schedule of fees payable for services rendered under the workmen's compensation schedule as a basis." This scheme of distribution applied to the \$18 annual fee for an individual would give \$3.60 for administration, \$8.64 for the capitation fee for general practitioners and \$5.70 for consultants, x-ray and laboratory service. The amount available per person for physicians on the family rate would be still less. A physician who enters into this agreement can terminate his participation only after giving the corporation notice in writing "and such termination shall not be effective until thirteen months from the date of such notice." There is no deductible clause or limit to the amount of services which may be demanded and given during a contract year. The physician is to be paid, as explained, approximately 48 per cent of the subscriber's premiums regardless of the amount of service the physician gives to the subscriber.

OFFICIAL NOTES

RADIO BROADCASTS

"Doctors at Work" is the title of the sixth annual series of dramatized radio programs being presented by the American Medical Association and the National Broadcasting Company.

The series opened Wednesday, November 13, and will run for thirty consecutive weeks, closing with a broadcast from the A. M. A. meeting at Cleveland on June 3, 1941. The program is scheduled for 10:30 p. m. eastern standard time (9:30 central, 8:30 mountain, 7:30 Pacific time) over the Blue network, other N. B. C. stations and Canadian stations.

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the programs, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

Some radio stations may be unable to broadcast the program at the regular scheduled time and may transcribe and broadcast it at another hour or even on another day. It is advisable therefore to verify the time by reference to local newspapers or by telephoning the local Blue network stations.

The programs will dramatize what modern medicine offers the individual in the way of opportunities for better health and the more successful treatment of disease. Incidental to this main theme the programs will explain the characteristics of the different fields of modern medicine and its specialties.

Descriptive posters for local distribution may be had gratis from the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Program titles will be announced weekly in *THE JOURNAL* and monthly in *Hygeia*, the Health Magazine.

Tickets are available for each broadcast. Address the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Tickets are free, but a stamped self-addressed envelop should accompany requests.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

December 18.	A Stitch in Time.
December 25.	The Country Doctor.
January 1.	Otorhinolaryngologist.

THE CLEVELAND SESSION

Applications for Hotel Reservations

A list of Cleveland hotels together with the rates for rooms may be found on advertising page 36 of this issue of *THE JOURNAL*. With this list will be found an application form that may be used to secure reservations through the Subcommittee on Hotels of the Local Committee on Arrangements. This application form may be clipped and, when it is properly filled in, should be sent at once to Dr. Edward F. Kieger, Chairman of the Subcommittee on Hotels, Cleveland Convention and Visitors' Bureau, Inc., 1604 Terminal Tower, Cleveland, Ohio.

Those who expect to attend the annual session of the American Medical Association should send in their applications at the earliest possible time. Applicants for reservations are especially requested to include a second and a third choice in order that good accommodations may be assured if the desired reservation cannot be had at the hotel of preference. It will greatly expedite matters if requests for reservations are addressed directly to Dr. Kieger.

Motion Pictures in the Scientific Exhibit

The Committee on Scientific Exhibit announces that motion pictures in the Scientific Exhibit at the Cleveland session will be shown in areas provided for that purpose rather than in exhibit booths. Application blanks for a place on the motion picture program may be obtained from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Regional Meeting.—The Northeastern Division of the Medical Association of the State of Alabama met at Alexander City, October 10, with the Tallapoosa County Medical Society acting as host. The program included:

Dr. Henry Ernest Askin, Alexander City, Convulsions.
Dr. James R. Garber, Birmingham, Diagnosis in Obstetrics.
Dr. Amos C. Gipson, Gadsden, The Role of Allergy in Pediatric Practice.
Dr. James O. Morgan, Gadsden, Indications for Surgery in Peptic Ulcer.
Dr. George Knox Spearman, Anniston, Perennial Hay Fever.
Dr. James Marvin Washam, Talladega, Appendicitis.

ARKANSAS

District Meetings.—Dr. Augustus A. Street, Vicksburg, Miss., discussed "Duodenal Ulcer" before the Fifth Councilor District Medical Society in Camden, October 10, and Dr. William H. Anderson, Booneville, president of the Mississippi State Medical Association, "A Doctor's Duty to Himself, to His Fellow Men and to the Public."—The Second District Medical Society met in Batesville, October 14. Drs. William T. Pride, Memphis, Tenn., discussed "Some of the Common Difficulties in Obstetrics" and Darmon A. Rhinehart, Little Rock, "X-Ray Treatment for Menorrhagia."—The Third Councilor District Medical Society was addressed in Helena, October 24, by Drs. Robert Lyle Motley, Memphis, Tenn., on "Indication and Uses of Sulfanilamide, Sulfapyridine, Sulfathiazole"; David T. Hyatt, Little Rock, "Vitamin Therapy"; Alan G. Cazort, Little Rock, "Allergic Dermatitis," and William R. Brooksher, Little Rock, "Medical Preparedness." The dinner session was addressed by Dr. Downey L. Harris, St. Louis, on "Rabies."

CALIFORNIA

State Board of Examiners.—Dr. Hugo M. Kersten, Los Angeles, has been appointed a member of the state board of medical examiners, succeeding Dr. William R. Molony Sr., Los Angeles, whose term expired last January. Dr. Charles B. Pinkham, San Francisco, was reappointed.

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in California is required by law to register annually, on or before January 1, with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$2. Failure to pay the required fee within sixty days after January 1 works a revocation of a license, and thereafter a license may be reissued only after application and the payment of a \$10 penalty.

CONNECTICUT

Personal.—Dr. Hazen A. Calhoun Jr., Middletown, has been appointed health officer of Haddam, succeeding Dr. Noah A. Burr.—Dr. William F. Verdi, New Haven, has received the gold medal award of the New Haven Advertising Club for his "outstanding contributions to the community."

Annual Registration Due During January.—Every practitioner of medicine and surgery holding a license to practice in Connecticut is required by law to register during January with the state department of health and at that time to pay a fee of \$2. Licentiates who have retired from active practice or who live out of the state must register annually but need not pay a fee. A practitioner failing to register is liable to a fine of not more than \$5.

Society News.—The Association of Connecticut Tumor Clinics was addressed in Bridgeport, October 17, among others, by Drs. Berkley M. Parmelee on "Irradiation Therapy for Cancer of the Breast" and William L. Weadon, "Treatment of Local Recurrences and Metastases."—Francis John Worsley Roughton, Ph.D., lecturer on physicochemical aspects of physiology, University of Cambridge, England, lectured at a special meeting of the Yale Medical Society, November 19, in New Haven, on "Recent Work on the Chemistry and Functions of Carbonic Anhydrase."

DISTRICT OF COLUMBIA

Changes in Faculty.—Dr. Edward J. Cummings, associate professor of clinical ophthalmology, has been promoted to professor at Georgetown University School of Medicine, Washington, newspapers announce. Other promotions include Dr. William McC. Ballinger to associate professor of gastroenterology and Dr. Edgar W. Davis to professor of clinical surgery.

Course in Aviation Medicine.—The second annual post-graduate course in aviation medicine, including aviation ophthalmology, for graduates in medicine will be held at George Washington University School of Medicine, Washington, D. C., February 3-7. Nineteen guests will lecture on the following subjects, among others:

Physiologic Problems Incident to Flying.
Motility of the Eye.
Color Vision and Night Blindness.
Stereopsis and Depth Perception.
Fundus of the Eye.
Refraction.
Aniseikonia as It Relates to Aviation.
Otolaryngology in Relation to Aviation.
Effect of Altitude in Relation to Military Flying.
Interpretations of Neurologic Signs in Aviation.
Methods of Administration of Oxygen During Flights at High Altitudes.

FLORIDA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Florida is required by law to register annually, on or before January 1, with the secretary of the state board of health and at that time to pay a fee of \$1. A licentiate failing to register annually is liable to a fine of not more than \$50.

GEORGIA

Dr. Lahey to Give Memorial Lecture.—Dr. Frank H. Lahey, Boston, President-Elect of the American Medical Association, will deliver the second Floyd Wilcox McRae Memorial Lecture, December 16, before the Fulton County Medical Society, Atlanta. His subject will be "The Management of Gastric, Duodenal and Jejunal Lesions."

University News.—A sum of \$100,000 has been presented to the University of Georgia by S. Price Gilbert, former associate justice of the Georgia supreme court, to construct an infirmary building. According to the *New York Times*, the infirmary will be named in honor of Justice Gilbert's father, the late Dr. Jasper Newton Gilbert, who served with the medical corps of the Confederate Army in the Civil War and later was a country doctor in Georgia. Dr. Gilbert, who lived in Columbus, was graduated at the Medical College of Georgia, Augusta, in 1855.

ILLINOIS

Research Fellowships in Medicine and Dentistry.—The Graduate School of the University of Illinois has established four research fellowships to be awarded for one year in the fields of medicine and dentistry in Chicago at a stipend of \$1,200 a year (calendar year with one month's vacation). Fellows are eligible for reappointment in competition with the new applicants. Candidates for these fellowships must have completed a training of not less than eight years beyond high school graduation. This training may have been acquired in any one of the following ways, or the equivalent thereof:

1. Work leading to the B.S. and M.D. degrees (in some instances the candidates would have the M.D. degree, or an additional year or two of hospital training beyond the intern year).
2. Work leading to the B.S., M.S. and D.D.S. degrees.
3. Work leading to the B.S. or B.A. degree in a four year collegiate course and to the D.D.S. degree.
4. Work leading to the B.S., D.D.S. and M.D. degrees.

Candidates should indicate the field of research in which they are interested and submit complete transcripts of their scholastic credits, together with the names of three former science teachers as references. March 1 is the deadline for acceptance of applications. Announcement of the fellowship awards will be made April 1, becoming effective September 1. Formal application blanks may be secured from the Secretary of the Committee on Graduate Work in Medicine and Dentistry, 1853 West Polk Street, Chicago.

IOWA

Society News.—The Des Moines Academy of Medicine and the Polk County Medical Society was addressed, November 20, by Drs. James Barrett Brown, St. Louis, on "Traumatic Surgery" and Andrew C. Ivy, Chicago, "Relation of Physiology to Modern Medicine."

Personal.—Dr. Eric P. Pfeiffer, formerly of Oakville, has been appointed director of the vital statistics division of the state department of health, effective October 1.—Dr. Lester A. Royal, West Liberty, has been named governor of district 132 of Rotary International.

The Rockwood Lecture.—Dr. Isaac Starr, Milton Bixler Hartzell research professor of therapeutics, University of Pennsylvania School of Medicine, Philadelphia, gave the fourth annual Paul Reed Rockwood Lecture of the State University of Iowa College of Medicine in Iowa City, November 13. His subject was "The Ballistocardiogram; Its Contribution to Our Knowledge of the Commoner Diseases Affecting the Heart and Circulation."

LOUISIANA

Annual Renewal Due January 1.—Every practitioner of medicine and surgery holding a certificate to practice in Louisiana is required by law to have his certificate renewed annually, on or before January 1, by the secretary-treasurer of the state board of medical examiners and at that time to pay a fee of \$2. The board may by unanimous vote revoke any certificate not renewed.

Society News.—The meeting of the Louisiana Association of Pathologists, November 25, in New Orleans, was opened with an address by Dr. Edwin H. Lawson. Other speakers were Drs. Bjarne Pearson on "Carcinoma of the Cervix Uteri, Its Effect on the Urinary Tract"; Albert E. Casey, "Mitosis Counts in Neoplasia," and Joseph B. Pasternack, "Methods for Rapid Preparation of Paraffin Sections."—Among other speakers, Arthur O. Kastler, Ph.D., Drs. Samuel B. Nadler and Michael E. DeBakey presented a symposium on the recent advances in vitamins before the Orleans Parish Medical Society, November 11. A special scientific session was held with the U. S. Marine Hospital staff, November 22. Dr. John A. Trautman talked on "Sulfonamides in the Treatment of Gonorrhea in the Male" and Dr. William L. Smith presented a case report on a typhoid carrier.

MINNESOTA

Annual Registration Due During January.—Every practitioner of medicine and surgery holding a license to practice in Minnesota is required by law to register annually during January with the secretary of the board of medical examiners and at that time to pay a fee of \$2. A licentiate who practices without renewing his license is guilty of a misdemeanor and is liable to prosecution.

Tuberculosis Survey.—The Minnesota State Medical Association has selected Meeker County as the first county in which a statewide campaign to free Minnesota from tuberculosis will be launched. The plan calls for extending to adults through family groups the same preventive service now given to children in the public schools, using the Mantoux test. The project will be under the direction of the committee on tuberculosis of the state medical association, of which Dr. J. Arthur Myers, Minneapolis, is chairman. Cooperating agencies include the Minnesota Public Health Association, the bureau of tuberculosis of the state division of social welfare, the Meeker-Kandiyohi-Swift Counties Medical Society, the Meeker County Christmas Seal Committee and the state department of health.

Society News.—The Ramsey County Medical Society was addressed, November 25, by Drs. Emmett V. Kenefick, St. Paul, on "Leukemias and Leukemoid Reactions"; Alexander E. Brown, Rochester, "Recent Advances in Therapy by Sulfanilamide and Its Related Compounds," and Gordon R. Kamman, St. Paul, "The Rorschach Test as a Method of Personality Analysis."—The general staff of the Mayo Clinic met with the Olmsted-Houston-Fillmore-Dodge Counties Medical Society, November 6; the program was devoted to a symposium on first aid by the physician casually present at an accident. The speakers were Drs. John S. Lundy, John W. Pender, Edward B. Tuohy, Alfred W. Adson, Robert D. Mussey, Gordon B. New and Albert J. Lobb, LL.B., all of Rochester.

MISSOURI

Pilgrimage to Beaumont's Grave.—The annual birthday pilgrimage to William Beaumont's grave, sponsored by the St. Louis Medical Society, was held November 21. Alphonse M. Schwitalla, S.J., made the principal address; Mayor Bernard F. Dickmann placed a wreath on the grave for the city of St. Louis; Dr. Cyrus E. Burford, president of the state medical association, also placed a wreath, and Dr. Herbert S. Langsdorf as president represented the St. Louis City Medical Society.

NEW JERSEY

Interim Meeting of House of Delegates.—The first interim meeting of the house of delegates of the Medical Society of New Jersey was held in Newark, November 28. The following progress reports were presented: medical service administration, by Dr. Elton W. Lance, Rahway, president of the board of governors; medical preparedness committee, by Dr. Charles H. Schlichter, Elizabeth, chairman, and hospital relationships committee survey of outpatients, by Dr. Henry B. Decker, Camden, chairman. Dr. Harry R. North, Trenton, discussed a proposal to purchase a permanent home for the state society.

NEW YORK

New Tumor Clinic.—A tumor clinic has been organized at the Saratoga Hospital, Saratoga Springs, according to an announcement by the division of cancer control of the state department of health. Dr. Richard D. Bullard, Saratoga Springs, is executive officer of the new clinic, which is the thirty-sixth in the state, operated as a means of meeting the problem of cancer control in the state.

Annual Registration Due January 1.—Every practitioner of medicine and surgery in New York is required by law to apply annually, on or before January 1, to the secretary of the board of medical examiners for a certificate of registration, on application forms furnished by him, and to pay at that time a fee of \$2. The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives to receive and transmit to him such applications and fees. Practitioners are liable to severe penalties for failing to register and for continuing in practice thereafter.

New York City

Third Harvey Lecture.—A. Baird Hastings, Ph.D., Hamilton Kuhn professor and head of the department of biological chemistry, Harvard Medical School, Boston, will deliver the third Harvey Lecture of the current season at the New York Academy of Medicine, December 19. His subject will be "The Electrolytes of Tissues and Body Fluids."

Symposium on Chemotherapy.—The Long Island College of Medicine presented a symposium on chemotherapy, November 13. Arnold H. Eggerth, Ph.D., associate professor of bacteriology, opened the program with a historical introduction and other speakers were:

- George W. Raiziss, Ph.D., Philadelphia, Mode of Action of the Sulfonamides.
- Dr. Elliston Farrell, assistant clinical professor of medicine at Long Island College, Toxic Reactions.
- Dr. Charles B. Jones, instructor in surgery, Long Island, The Sulfonamides in Surgery.
- Dr. Yale Kneeland Jr., assistant professor of medicine, Columbia University College of Physicians and Surgeons, The Sulfonamides in Pneumonia.
- Dr. Alfred Cohn, New York City Department of Health, The Sulfonamides in Gonococcal Infections.
- Dr. Josephine B. Neal, clinical professor of neurology, Columbia, The Sulfonamides in Meningitis.
- Dr. Lewis A. Koch, clinical professor of pediatrics, Long Island, The Sulfonamides in Pediatric Practice.

NORTH DAKOTA

Personal.—Dr. Bertha B. Brainard, Jamestown, was recently appointed in charge of the student health service at Oregon State College, Corvallis.—Dr. Elvin L. Sederlin, formerly of Laramie, Wyo., has been appointed health officer of Fargo, to succeed Dr. Harvey J. Skarshaug, resigned.

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in North Dakota is required by law to register annually, on or before January 1, with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$5 if a resident of North Dakota, or \$2 if a nonresident. A practitioner may not lawfully practice if he has not registered. If he does so his license may be revoked and can be reinstated on the payment of unpaid fees and \$0.50 for each month of default.

OHIO

Dr. Hudson Goes to France.—Dr. Noel Paul Hudson, professor of bacteriology at Ohio State University College of Medicine, Columbus, has been granted a year's leave of absence to join a health commission of the Rockefeller Foundation to work in France. With other members of the commission Dr. Hudson was to leave late in October. He had previously served with the International Health Division of the Rockefeller Foundation. During the World War he served in France as a lieutenant in the Sanitary Corps of the Medical Department, U. S. Army.

Postgraduate Course in Toledo.—The Academy of Medicine of Toledo and Lucas County presented its annual postgraduate course of lectures, December 11-13, with Dr. Andrew C. Ivy, Nathan Smith Davis professor of physiology and professor of pharmacology, Northwestern University Medical School, Chicago, as the lecturer. Dr. Ivy's subjects included: physiologic changes in pregnancy, physiology of labor, the liver and biliary tract, water balance in health and disease, advances in diagnosis and therapeutic interest in the alimentary tract, hypertension, effects of various drugs on peripheral circulation, and heart failure.

PENNSYLVANIA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Pennsylvania is required by law to register annually, on or before January 1, with the board of medical education and licensure in the department of public instruction and to pay a fee of \$1 or such fee as may be fixed by the department of public instruction. A practitioner who fails to register and who continues to practice is liable to a fine of from \$10 to \$100.

Special School to Extend Research.—The assets of the Devereux Schools, Devon, have been transferred to the Devereux Foundation, recently established by the founder of the schools, Helena T. Devereux. The foundation will continue to operate the schools and will increase the activities to include research, the further study and treatment of children through psychiatry and psychology and the establishment of scholarships. The schools have ten units and care for more than 200 children. The foundation will be under the direction of a board of trustees including Drs. Louis R. Kaufman, New York; Fred C. Aldridge, Wayne; Gabriel Henry Katz and Edward M. Westburg, Ph.D., of the Institute of the Pennsylvania Hospital, Philadelphia.

Philadelphia

Women's Cancer Forum.—The annual cancer forum presented to the public by the Women's Auxiliary to the Lankenau Hospital Research Institute, assisted by District No. 1 of the Pennsylvania State Nurses' Association, was held November 25-26 at the Bellevue-Stratford Hotel. Among the speakers were:

- Dr. Eugene P. Pendergrass, The Cyclotron—Newest Instrument to Study Cancer and Other Medical Problems.
- Otto C. Glaser, Ph.D., Amherst College, Amherst, Mass., The Relation of Biology and the Growth Problem to Cancer.
- Dr. Catharine Macfarlane, Further Report on the Reexamination of One Thousand Volunteers.
- Dr. Nathaniel Volney Ludwick, The Leukemias.
- Dr. Temple S. Fay, Further Observations on Refrigeration in Cancer.

Society News.—Drs. Frederick A. Bothe and Richard H. Meade Jr. addressed the Philadelphia Academy of Surgery, November 4, on "Mesenteric Adenitis" and "Healing of Abdominal Wounds in Perforated Peptic Ulcers" respectively. —Drs. Gabriel Tucker and Ernest A. Spiegel, among others, addressed the Philadelphia Laryngological Society, November 5, on "Hoarseness, Its Mechanism, Clinical Significance, Clinical Signs and Treatment" and "Reaction of the Labyrinth to Rhythmically Interrupted Currents" respectively. —Dr. John F. Fulton, New Haven, Conn., delivered the eighth S. Weir Mitchell Oration before the College of Physicians of Philadelphia, November 6, on "Neurology and War." —Speakers before the Obstetrical Society of Philadelphia, November 7, were Drs. Charles Mazer and Elkin Ravetz on "Effect of Combined Administration of Chorionic Gonadotropin and the Pituitary Synergist on the Human Ovaries," and Clifford B. Lull, "Pubertis Praecox Due to Ovarian Tumor."

RHODE ISLAND

Society News.—Dr. Shields Warren, Boston, addressed the Providence Medical Association, December 2, on "Medicolegal Aspects of Malignant Diseases." —Dr. John F. Kenney will address the Pawtucket Medical Association, December 19, on electrocardiography.

Personal.—Dr. Hilary J. Connor, Providence, has been appointed director of a new department for venereal disease control in the state health department. —Dr. Halsey DeWolf, Providence, has been appointed to the advisory state council of defense to coordinate state defense activities with those of the federal government and Dr. Albert H. Jackvony, Providence, has been made a member of the state selective service appeal board.

TEXAS

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Texas is required by law to register annually, on or before January 1, with the state board of medical examiners and at that time to pay a fee of \$2. If a practitioner fails to renew his registration within sixty days after January 1, his license is suspended.

VIRGINIA

Mental Hygiene Meeting.—Dr. David C. Wilson, Charlottesville, was elected president of the Mental Hygiene Society of Virginia at the annual meeting in Richmond, October 31. Guest speakers at the meeting were Drs. Frank J. Curran, New York, and Joseph E. Barrett, clinical director of Southwestern State Hospital, Marion, who discussed problems of the adolescent and Lawrence Kolb, U. S. Public Health Service, treatment and research in the field of mental disease.

Hospital Changes.—Dr. Grover C. Godwin, Sanatorium, N. C., has been named director of the Roanoke City Tubercular Sanatorium to succeed Dr. John E. K. Flannagan, resigned. —Dr. Samuel E. Hughes, medical director of the Hilltop Sanatorium, Danville, for many years, has resigned, it is reported. —Dr. Willard L. Quennell, has been appointed medical director of the Norfolk General Hospital to succeed Dr. Arthur H. Perkins, resigned.

GENERAL

Meeting of Insurance Physicians.—Dr. Donald B. Cragin, Hartford, Conn., was elected president of the Association of Life Insurance Medical Directors at the annual meeting in Boston, October 16-18. Dr. David E. W. Wenstrand, Milwaukee, became first vice president and Dr. William Bolt, New York, second vice president. Dr. Edwin G. Dewis, Newark, N. J., remains as secretary. Speakers, all of Boston, included Drs. Maurice B. Strauss, on "Disorders Due to Nutritional Deficiency"; Chester S. Keefer, "The Present Status of Chemotherapy in the Treatment of Infectious Diseases," and Merrill Moore, "Alcohol, a Medical Problem."

Southern Psychiatric Meeting.—Dr. Whitman C. McConnell, St. Petersburg, Fla., was named president-elect of the Southern Psychiatric Association at its annual meeting in Jacksonville, Fla., October 21-22, and Dr. Arthur J. Schwenkenberg, Dallas, Texas, was installed as president. Dr. James K. Hall, Richmond, Va., was elected vice president and Dr. Newdigate M. Owensby, Atlanta, Ga., reelected secretary. The 1941 convention will be in Nashville. Among speakers at the meeting were:

- Dr. Henry Mason Smith, Tampa, Fla., The Psychological and Economic Influence of Alcohol.
- Dr. Gilbert Christian Anderson, New Orleans, The Dental and Oral Basis of Certain Neuropsychiatric States.
- Dr. Francis J. Tartaglino, Washington, D. C., Psychotic Reactions Following Sulfanilamide Administration.
- Dr. Louis Michael Foltz, Lakeland, Ky., Involutional Melancholia and Its Connection to Gonadotropic Hormone Stimulation.
- Dr. Owensby, Homosexuality Corrected by the Pharmacologic Shock Method.

Neuropsychiatric Meeting in Milwaukee.—The Central Neuropsychiatric Association held its nineteenth annual meeting at the Hotel Pfister, Milwaukee, October 25-26, under the presidency of Dr. Percival Bailey, Chicago. Among the speakers were:

- Dr. Otto H. Foerster, Milwaukee, Self-Inflicted Lesions of the Skin.
- Dr. Max J. Fox, Milwaukee, Treatment of Bulbar and Upper Cervical Types of Poliomyelitis by Perivascular Drainage.
- Dr. Theodore L. Squier, Milwaukee, Emotional Factors in Allergic States.
- Dr. Andrew I. Rosenberger, Milwaukee, Observations on Treatment of Amyotrophic Lateral Sclerosis (Leukopolymyopathy) with Vitamin E.

A symposium on shock therapy was presented by Drs. Lloyd H. Ziegler, James A. Alston, Carroll W. Osgood, Michael Kasak, Harold T. Schroeder, Wauwatosa, and Jack L. Kinsey, Milwaukee. Officers elected were Drs. Louis J. Karnosh, Cleveland, president; Mabel G. Masten, Madison, Wis., vice president, and William C. Menninger, Topeka, Kan., secretary, reelected. The 1941 meeting will be in Detroit and Ann Arbor, Mich.

Influenza Epidemic.—An epidemic of mild influenza has been prevalent in California, reaching its peak during the first week of December. A total of 1,800 cases was reported for December 7, according to the newspapers. Thousands of persons have been stricken since the outbreak began in November. On December 5 the epidemic was said to have spread into

CORRECTION

Roentgenologic Technicians Instead of Roentgenologists.—In the current comment in *THE JOURNAL* (November 16, p. 1724) appears a statement beginning "The technical branches associated with medical care include physical therapists, roentgenologists, clinical pathology technicians, lay anesthetists, . . ." In this item the word "roentgenologists" should have been "roentgenologic technicians."

LONDON

(From Our Regular Correspondent)

Oct. 26, 1940 (delayed).

The Centenary of the British Medical Journal

Britons have been informed that the bombing of our cities and, at times, even villages is not due to any wish to destroy life and property but is really humanitarian, a means of bringing about a revolution and so ending the war! But, as foreign visitors confirm, all our activities continue with remarkable normality and calmness, though of course the war has altered some of our routine. The medical journals are a little shorter, because of the need to economize paper, but, excepting two local ones, they appear with their usual regularity. The *British Medical Journal* has not allowed the war to interfere with the celebration of its centenary. It publishes a reproduction of the "Introductory Address" of the first number (Oct. 3, 1840) of the *Provincial Medical and Surgical Journal*, which was its direct ancestor. The sentiments of the address are admirable and in no way out of date, but they are expressed with a verbosity which is now obsolete. In January 1857 the title *British Medical Journal* was adopted. The high standard, scientific and practical, always maintained by able editors and eminent contributors, is well known. In an editorial it is stated that this second year of the war finds Britain "an embattled country subject to perpetual air alarms and threatened with invasion, and the treatment of civilian air casualties is a matter of daily concern to doctors throughout the land. The future is obscure; but British hearts are stout." Many messages of congratulation from eminent members of the profession, from the editors of other journals published in the commonwealth and from the Editor of THE JOURNAL A. M. A. are published.

American and Canadian Physicians to Be Licensed for the Duration of the War

The government has made an order under the Emergency Powers Act, passed for the purposes of the war, enabling the General Medical Council to register for the period of the emergency Canadian and United States physicians. They will thus be able to join the Emergency Medical Service with the same privileges as British physicians. Previously we have never had medical reciprocity with the United States and only partial reciprocity with Canada, owing to difficulties which arose from the medical autonomy of the Canadian provinces. Applicants for the new registration must be British subjects or citizens of the United States, be of good character, and must hold some medical diploma recognized for the time being for the purposes of this order by the British General Medical Council as furnishing a guaranty of sufficient knowledge and skill for the efficient practice of medicine, surgery and midwifery.

Science and the War

In order to insure the fullest cooperation of scientific workers with the government in the national war effort a scientific advisory committee has been appointed after discussion with the Royal Society. The committee consists of the following, among whom medical science is represented: Sir William Bragg, president of the Royal Society; E. V. Appleton, F.R.S. (physicist), secretary of the Department of Scientific and Industrial Research; Sir Edward Mellanby, F.R.S. (physiologist), secretary of the Medical Research Council; Sir Edwin Butler, F.R.S., secretary of the Agricultural Council; Prof. A. V. Hill (physiologist), physical secretary of the Royal Society; Prof. A. G. Egerton, F.R.S., biologic secretary of the Royal Society.

The terms of reference of the committee are (1) to advise on any scientific problem referred to them, (2) to advise government departments on the selection of persons for particular lines of scientific inquiry or membership of committees on which scientists are required and (3) to bring to notice promising new scientific or technical developments which may be important in our war effort.

A Bombed Hospital

The following is an example of what hospitals have to go through: A bomb fell on an emergency hospital in south-eastern England, killing some patients who had been evacuated from bombed London hospitals. The bomb crashed through three wards, and many patients were buried amid tons of wreckage. The fire department freed some of them, and while the bombers were still overhead the nurses worked among the debris, bringing mattresses and administering morphine to trapped patients.

The Feeding of the Army

The Select Committee on National Expenditure has received a report from its subcommittee on army services recommending the greater use of canned foods. Evidence was received indicating the advantages of providing the army with more fruits and vegetables. The subcommittee considers that during the winter a position of extreme complexity and difficulty may arise, owing to the fact that numbers of troops will have to be accommodated in billets and hutsments and that efficient catering will play a conspicuous role in maintaining the physical condition and morale of the troops. Canned and prepared foods would give increased variety and in many cases supply the troops with food that merely requires heating, for which skilled cooks would not be required.

A Second Contingent of the American Hospital Unit

The second contingent of the American Hospital Unit, financed by the Allied Relief Fund, has arrived. The vessel in which it came encountered a violent Atlantic storm and as there was no ship's doctor the unit attended the casualties caused among the passengers and crew. The party consists of a surgeon and a physician who are brothers, a radiographer, four nurses and a laboratory technician. There is Dr. Henry Heyl, a 34 year old neurosurgeon, who has trained for eight years under Dr. Jason Mixer and Dr. Gilbert Horrax, leading neurosurgeons. His brother Dr. James Heyl specializes in internal medicine and research work. The radiographer, Mr. William Wykoff, was in Finland during the Russian invasion. He and one of the nurses made their way back to America through Germany and Lisbon.

Marriages

WILLIAM PROVINCE MCGUIRE, Winchester, Va., to Miss Dorothy Elizabeth Robinson of Glen Rock, N. J., at Ridgewood, N. J., October 19.

JOHN THORNTON MITCHELL, Miami, Fla., to Miss Marie Hammond of La Grange, Ga., in Fort Lauderdale, Fla., in October.

CLARENCE S. BOLENDER, Clearwater, Fla., to Mrs. Carrie Weaver Waddell of Cambridge City, Ind., September 18.

WILLIAM EDWARD STEINER, Savanna, Ill., to Miss Marie Melanie Kolbus of Chicago in September.

GROVER CLEVELAND WRENN, Siler City, N. C., to Miss Virginia Gaddy in Raleigh, October 20.

PLINY AUSTIN PRICE, Toledo, Ohio, to Miss Margaret Marie Harrigan of Columbus in October.

PHILLIP BROWER PARSONS, Charlotte, N. C., to Miss Annette Barnes of Elm City, October 12.

ERNEST DE WITT RICHARD PONZER to Miss Elizabeth Parkin, both of Chicago, September 21.

HENRY PLETCHER CLOSE to Miss Mary Dorothy Quinn, both of Philadelphia, October 1.

Deaths

Le Roy Long * Oklahoma City; Louisville (Ky.) Medical College, 1893; member of the House of Delegates of the American Medical Association, 1903, 1904 and 1920; demonstrator of genito-urinary diseases at his alma mater, 1894-1895; dean and professor of surgery, University of Oklahoma School of Medicine, 1915-1931; past president of the Oklahoma State Medical Association and the Oklahoma County Medical Society; member of the Western Surgical Association and of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; member of the state board of medical examiners from 1911 to 1915; served during the World War; surgeon, St. Anthony's Hospital; aged 71; died, October 27.

Walter Edward List, Cincinnati; Medical College of Ohio, Cincinnati, 1907; member of the Ohio State Medical Association; superintendent of the Jewish Hospital; formerly superintendent of the Minneapolis General Hospital; trustee of the American Hospital Association from 1935 to 1937; on the editorial board of *Hospitals*, the Journal of the American Hospital Association; fellow of the American College of Hospital Administrators; aged 54; died, October 26, of coronary occlusion.

Frederick Woltmann, Kampsville, Ill.; Hahnemann Medical College and Hospital, Chicago, 1903; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; member of the Illinois State Medical Society; served during the World War; aged 64; died, October 7, in the Veterans Administration Facility, Jefferson Barracks, Mo., of melanotic sarcoma.

Edwin Minor Huston * Dayton, Ohio; Medical College of Ohio, Cincinnati, 1896; past president of the Ohio State Medical Association and the Montgomery County Medical Society; formerly member of the board of education; for many years on the staff of the Miami Valley Hospital; aged 75; died, October 22, in Malone, N. Y., of carcinoma of the stomach.

George Washington Strickland, Roselle, N. J.; Long Island College Hospital, Brooklyn, 1895; member of the Medical Society of New Jersey; formerly member of the school board; aged 75; for many years on the staff of St. Elizabeth Hospital and Elizabeth General Hospital, Elizabeth, where he died, October 2, of cerebral hemorrhage and myocarditis.

Isadore Bernard Rothstein * Newark, N. J.; University and Bellevue Hospital Medical College, New York, 1923; member of the American Academy of Pediatrics; aged 40; on the staff of the Irvington (N. J.) General Hospital, Babies' Hospital-Coit Memorial and the Newark Beth Israel Hospital, where he died, October 22, of malignant nephrosclerosis.

Louis Charles Deane * San Francisco; Cooper Medical College, San Francisco, 1891; member of the Pacific Coast Ophthalmological Society; for many years visiting surgeon to the Stanford University Hospital; on the staff of the Mount Zion Hospital from 1912 to 1926; aged 69; died, October 17, of coronary occlusion and chronic myocarditis.

Frederick William Bailey, Manhasset, N. Y.; State University of Iowa College of Medicine, Iowa City, 1905; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; formerly on the staffs of St. Luke's and Mercy hospitals, Cedar Rapids, Iowa; aged 62; died, October 11.

Harry Clay Sharp, Lyons, N. J.; University of Louisville (Ky.) Medical Department, 1893; in 1909 delegate of the American Medical Association; served during the World War; at one time on the staff of the Indiana Reformatory, Jeffersonville, Ind.; on the staff of the Veterans Administration Facility; aged 70; died, October 31, of myocarditis.

Jacob Schultz, Middlesboro, Ky.; Hospital College of Medicine, Louisville, 1906; member of the Kentucky State Medical Association; past president of the Bell County Medical Society; on the staff of the Middlesboro Hospital; aged 60; died, October 3, in the Johns Hopkins Hospital, Baltimore, of septicemia and infection of the urinary tract.

Raymond Brewer Parker * Winthrop, Mass.; Harvard Medical School, Boston, 1912; chairman of the board of health and school physician; president of the staff of the Winthrop Community Hospital; served during the World War; aged 54; died, October 19, of coronary thrombosis, arteriosclerosis, chronic nephritis and hypertension.

Hugh Alexander Chisholm, Halifax, N. S., Canada; McGill University Faculty of Medicine, Montreal, Que., 1905; served during the World War; at one time inspector of health

of Nova Scotia and member of the department of pensions and national health; formerly port physician of Halifax; aged 57; died, September 25.

William John Bierer, Kittanning, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1897; member of the Medical Society of the State of Pennsylvania; past president of the Armstrong County Medical Society; county medical director; for many years a member of the school board; aged 67; died in October.

James Lawrence Thompson, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1889; member of the South Carolina Medical Association and the American Psychiatric Association; on the staff of the South Carolina State Hospital; aged 86; died, September 24, of arteriosclerosis.

William Bruce Almon, Halifax, N. S., Canada; Halifax Medical College, 1899; associate professor of obstetrics emeritus at his alma mater, now the Dalhousie University Faculty of Medicine; formerly visiting physician, Infectious Disease Hospital; at one time health officer; aged 65; died, September 11.

Albert Alton Getman * Syracuse, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York, 1915; fellow of the American College of Physicians; on the staff of the General Hospital; aged 52; died, October 28, in the Strong Memorial Hospital, Rochester, of cerebral arteriosclerosis.

Albert Clark Benedict, Yonkers, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1871; member of the Medical Society of the State of New York; for many years police surgeon; formerly on the staff of St. Joseph's Hospital; aged 96; died, October 29.

George Andrew Sarchet, Mobridge, S. D.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1901; member of the South Dakota State Medical Association; served during the World War; on the staff of the Mobridge Hospital; aged 66; died, September 21, of carcinoma of the larynx.

Walter Redmon Pinnell, Mount Sterling, Ky.; University of Louisville (Ky.) Medical Department, 1907; member of the Kentucky State Medical Association; past president of the Montgomery County Medical Society; aged 54; died, October 2, in the Good Samaritan Hospital, Lexington, of nephritis.

Bruno Joseph Sawicki, Detroit; Toledo Medical College, 1913; Detroit College of Medicine and Surgery, 1917; member of the Michigan State Medical Society; served during the World War; aged 51; died, October 11, in the Mercy Hospital, Bay City, of injuries received in an automobile accident.

Simon Gunerus Gill, New Orleans; University of Louisiana Medical Department, New Orleans, 1878; at one time a pharmacist; formerly quarantine inspector for the state board of health at Port Eads, La.; aged 95; died, October 23, of malignant papilloma of the bladder and chronic myocarditis.

Francois X. L. de Martigny, Montreal, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1893; served during the World War; formerly on the staff of the Hôpital Ste. Jeanne d'Arc; aged 68; died, September 28.

Henry Bettis Malone, Chester, S. C.; North Carolina Medical College, Charlotte, 1909; member of the South Carolina Medical Association; served during the World War; was chairman of the county board of health; aged 65; died, October 8, of bronchiectasis and heart disease.

Donald Wallace Skeel * Los Angeles; University of Southern California College of Medicine, Los Angeles, 1899; medical director of the Occidental Life Insurance Company; served during the World War; aged 67; died, October 11, of coronary thrombosis and arteriosclerosis.

David Kaufman, Altoona, Pa.; Jefferson Medical College of Philadelphia, 1908; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 55; on the staffs of the Altoona Hospital and the Mercy Hospital, where he died, October 22, of leukemia.

Gustave A. Ozenne, Winfield, Ala.; University of the South Medical Department, Sewanee, Tenn., 1906; member of the Medical Association of the State of Alabama; aged 57; died, October 24, in a hospital at Birmingham of retroperitoneal hemorrhage and intestinal obstruction.

Abraham Turner Hubbell * Wood River, Neb.; Chicago Homeopathic Medical College, 1903; Northwestern University Medical School, Chicago, 1905; aged 62; associate member on the staff of St. Francis Hospital, Grand Island, where he died, October 18, of coronary embolism.

Ralph Kable Collins, New York; Johns Hopkins University School of Medicine, Baltimore, 1922; member of the staff of the International Health Division of the Rockefeller Foundation; aged 46; died, October 1, at the Rockefeller Institute Hospital of pulmonary embolus.

Howard Wilbert Nowell ☉ Brookline, Mass.; Boston University School of Medicine, 1911; instructor in pathology at his alma mater from 1911 to 1913 and associate professor from 1913 to 1915; aged 68; died, October 28, in Ogunquit, Maine, of chronic myocarditis.

John Aquaro, New York; Columbia University College of Physicians and Surgeons, New York, 1898; served during the World War; at one time inspector for the department of health, and physician on the staff of the department of correction; aged 64; died, October 15.

William Johnstone Thomson, Broadmoor, Colo.; Northwestern University Medical School, Chicago, 1899; member of the Colorado State Medical Society; served during the World War; aged 66; died, October 14, in the Glockner Hospital, Colorado Springs.

Samuel Augustus Scott, Eudora, Ark.; University of Louisville (Ky.) Medical Department, 1877; Medical Department of Tulane University of Louisiana, New Orleans, 1894; aged 87; died, October 14, in Vicksburg, Miss., of pernicious anemia and arteriosclerosis.

Clinton Durham Fife ☉ Dayton, Ohio; Western Reserve University Medical Department, Cleveland, 1921; fellow of the American College of Physicians; on the staffs of the Miami Valley and Good Samaritan hospitals; aged 45; died, October 24, of uremia.

Lorin W. Smith, Hastings, Minn.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; member of the Indiana State Medical Association; at one time mayor of Wabash, Ind.; aged 75; died, October 8, of chronic myocarditis and nephritis.

Gaston Torrance, Birmingham, Ala.; University of Virginia Department of Medicine, Charlottesville, 1897; member of the Medical Association of the State of Alabama and the Southern Surgical Association; aged 72; died, October 18, of pneumonia.

Archie L. Shanks, Hannibal, Mo.; Washington University School of Medicine, St. Louis, 1901; member of the Missouri State Medical Association; aged 65; on the staff of St. Elizabeth's Hospital, where he died, October 23, of coronary occlusion.

Leo Earle Wilson, Stamford, Conn.; University of Vermont College of Medicine, Burlington, 1928; member of the Connecticut State Medical Society; aged 37; died, October 13, of ruptured esophageal varices with hemorrhage and Laënnec's cirrhosis.

Dickson Leonard Moore, Columbus, Ohio.; University of Wooster Medical Department, Cleveland, 1892; member of the Ohio State Medical Association; for many years on the staffs of the Grant and Children's hospitals; aged 77; died, September 27.

Marian H. Frauenthal Sloane ☉ New York; University and Bellevue Hospital Medical College, New York, 1930; on the staffs of the Hospital for Joint Diseases and the New York Infirmary for Women and Children; aged 35; died, September 23.

Allen Gilbert Ireland ☉ Trenton, N. J.; Medical School of Maine, Portland, 1918; formerly member of the state department of public instruction; aged 40; died, October 23, in the University Hospital, Philadelphia, of glioma of the left temporal lobe.

William James Jolly ☉ Oklahoma City; Medical College of the State of South Carolina, Charleston, 1882; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; aged 91; died, September 24.

Elliott Thompson Jett, Falmouth, Va.; University of Virginia Department of Medicine, Charlottesville, 1889; aged 71; died, October 17, in the Mary Washington Hospital, Fredericksburg, of strangulated inguinal hernia and intestinal obstruction.

Samuel Ellsworth Blair, Alford, Iowa; State University of Iowa College of Medicine, Iowa City, 1894; member of the Iowa State Medical Society; aged 73; died, October 8, in the McKennan Hospital, Sioux Falls, S. D., of coronary sclerosis.

Thomas H. Wood, Bell Buckle, Tenn.; University of Nashville Medical Department, 1886; member of the Tennessee State Medical Association; president of the Bedford County Medical Society; for many years mayor; aged 73; died, October 18.

James Coleman Fisher, Jefferson, Ohio; Rush Medical College, Chicago, 1889; on the board of trustees of Millikin University from 1904 to 1930; aged 82; died, October 27, in the Ingleside Hospital, Cleveland, of valvular heart disease.

Theodore Henry Smith, Detroit; Detroit College of Medicine, 1896; member of the American Urological Association; served during the World War; on the staff of the Harper Hospital; aged 65; hanged himself, September 30.

Wilmoth Osborne ☉ New York; University of Oregon Medical School, Portland, 1924; on the staff of the New York Hospital; aged 44; died, September 12, in the Presbyterian Hospital of metastatic carcinoma of the brain.

Leslie Guy Eastman Hazen, N. D.; Hering Medical College, Chicago, 1903; member of the North Dakota State Medical Association; past president of the North Dakota Sixth District Medical Society; aged 67; died, September 21.

Leonard William Brown, Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1903; member of the Indiana State Medical Association; aged 64; died, October 5, in St. Vincent's Hospital of coronary occlusion.

Robert Henry Martin, Magnetic Springs, Ohio; McGill University Faculty of Medicine, Montreal, Canada, 1896; member of the Ohio State Medical Association; aged 65; died, October 30, in the University Hospital, Columbus.

Jessica Royce Carleton, Ambala, Punjab, India; Woman's Medical College of Pennsylvania, Philadelphia, 1886; medical missionary; for many years director of the Philadelphia Hospital for Women; aged 78; died, October 23.

James Leslie Passmore, Detroit; Michigan College of Medicine and Surgery, Detroit, 1906; veteran of the Spanish-American and World wars; aged 60; died, October 19, in the Receiving Hospital of cerebral hemorrhage.

Chester Dare Lee, Donelson, Tenn.; Vanderbilt University School of Medicine, Nashville, 1914; superintendent of the Tennessee Home and Training School for Feeble-minded; aged 57; died, October 16, of cerebral hemorrhage.

Charles Frederick Roan ☉ Chicago; University of Illinois College of Medicine, Chicago, 1928; on the staffs of the Augustana Hospital and the Lutheran Deaconess Hospital; aged 41; died, October 12, of coronary thrombosis.

Alan Greenleaf Terrell, Riverhead, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1892; formerly health officer; aged 74; hanged himself, October 9, in Southampton.

Edward J. Murphy ☉ Philadelphia; Jefferson Medical College of Philadelphia, 1906; on the staffs of the Jewish Hospital, St. Mary's Hospital and the Germantown Dispensary and Hospital; aged 55; died, September 21.

Frederick Remington Johnson ☉ New York; Columbia University College of Physicians and Surgeons, New York, 1936; aged 32; was killed, September 18, in an automobile accident near New Milford, Conn.

Virgil Dark, Opelika, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1911; member of the Medical Association of the State of Alabama; aged 53; died, September 18, in Alexandria City.

Daniel H. Fondren, Maben, Miss.; Memphis (Tenn.) Hospital Medical College, 1893; member of the Mississippi State Medical Association; aged 71; died, October 13, in the Houston (Miss.) Hospital of heart disease.

Zachary Taylor Pinner, Pomaria, S. C.; Chattanooga (Tenn.) Medical College, 1905; member of the South Carolina Medical Association; aged 62; died, October 18, in a hospital at Columbia of pneumonia.

Raymond Clark Breece, Grand Rapids, Mich.; Michigan College of Medicine and Surgery, Detroit, 1905; served during the World War; aged 61; died, October 8, in the Michigan Soldiers' Home Hospital.

Anthony Joseph Villone, Quincy, Mass.; Tufts College Medical School, Boston, 1918; member of the Massachusetts Medical Society; aged 49; died, October 6, in the City Hospital of coronary thrombosis.

Richard Frederick Codrington, Richland, Mich.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1902; aged 85; died, October 25, in the Borgess Hospital, Kalamazoo, of cirrhosis of the liver.

Lee Alfred Hays, Columbus, Ohio; Eclectic Medical College, Cincinnati, 1910; served during the World War; aged 58; died, October 30, in the White Cross Hospital, Columbus, of cerebral hemorrhage.

DEATHS

JOUR. A. M. A.
Dec. 14, 1931

Clifford Gordon Engle * Henderson, Texas; Eclectic Medical College, Cincinnati, 1920; aged 47; died, October 14, in a hospital at Natchitoches, La., of injuries received in an automobile accident.

Thomas James O'Brien, Pawtucket, R. I.; College of Physicians and Surgeons, Baltimore, 1912; on the staffs of the Homeopathic and St. Joseph's hospitals, Providence; aged 51; died, September 22.

Chester Ambrose Wilkinson * Kendall, Mich.; Jefferson Medical College of Philadelphia, 1888; aged 78; on the staff of the Bronson Hospital, Kalamazoo, where he died, October 11, of heart disease.

John Charles Emme, Harlan, Ind.; Indiana University School of Medicine, Indianapolis, 1912; aged 50; died, October 25, in the Lutheran Hospital, Fort Wayne, of cardiovascular renal disease.

Laurence Clarke Swan * Beverly, Mass.; Harvard Medical School, Boston, 1907; served during the World War; aged 59; on the staff of the Beverly Hospital, where he died, October 2, of embolism.

Walter V. Lunsford, Pueblo, Colo.; Ensworth Medical College, St. Joseph, Mo., 1891; aged 85; died, September 9, in the Parkview Hospital of acute myocarditis and pulmonary tuberculosis.

Charles Benjamin Shotwell, Richmond, Mo.; Rush Medical College, Chicago, 1883; member of the Missouri State Medical Association; aged 83; died, October 12, of bronchopneumonia.

Margaret O'Hara, Smith's Falls, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1891; for many years Presbyterian medical missionary in India; aged 85; died, August 27.

Tallulah S. Tucker, Memphis, Tenn.; Indiana Eclectic Medical College, Indianapolis, 1887; aged 78; died, September 21, in the Baptist Hospital of cholecystectomy following jaundice.

Ransom Lee Carr, Rosehill, N. C.; Baltimore Medical College, 1907; formerly member of the state legislature and county health officer; aged 62; died, October 17, of arteriosclerosis.

Robert Eugene Forster, Chicago; Magyar Királyi Erzsébet Tudományegyetem Orvostudományi, Pecs, Hungary, 1923; aged 40; was found dead, October 30, of poison, self administered.

Gisela Von Poswik * Scranton, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1911; member of the American Roentgen Ray Society; aged 65; died, October 2.

Le Roy Willis, Central City, Ky.; Kentucky University Medical Department, Louisville, 1905; member of the Kentucky State Medical Association; aged 58; died, September 5.

Francis Lawrence Oswald, New York; University of the City of New York Medical Department, 1894; veteran of the Spanish-American War; aged 75; died, September 27.

Harvey Alfred Berkes * Los Angeles; Western Reserve University Medical Department, Cleveland, 1909; past president of the Hollywood Hospital; aged 58; died, October 30.

Raymond Eugene Robinson, Chicago; University Medical College of Kansas City, Mo., 1913; served during the World War; aged 50; died, October 2, of pulmonary embolism.

Charles Henry Curran, Springfield, Mass.; University of the City of New York Medical Department, 1886; died, September 10, of chronic myocarditis and arteriosclerosis.

James Rosser Bedford, Dahinda, Ill.; Rush Medical College, Chicago, 1881; Civil War veteran; aged 94; died, October 19, in Onaida of cerebral hemorrhage and pneumonia.

Charles E. Beitmen, Kendrick, Okla.; St. Louis College of Physicians and Surgeons, 1903; also a druggist; aged 73; died in October in Oklahoma City of cerebral hemorrhage.

James Alexander Murray, Victoria, B. C., Canada; Halifax (N. S.) Medical College, 1905; served with the Canadian Army during the World War; aged 59; died, August 27.

Frank Algan Duston, St. Stephen, N. B., Canada; Harvard Medical School, Boston, 1911; on the staff of the Chipman Memorial Hospital; aged 62; died, September 12.

Marion G. Wilbur, Chicago; Medical College of the State of South Carolina, Charleston, 1902; member of the Illinois State Medical Society; aged 68; died, October 8.

Eric Lafcadio Nye, Amarillo, Texas; University of Kansas School of Medicine, Kansas City, 1937; aged 30; died, October 24, of heart disease and pulmonary tuberculosis.

Frank Walter Shaw, Gimli, Man., Canada; University of Manitoba Faculty of Medicine, Winnipeg, 1920; aged 52; died, October 26, of hypertension and arteriosclerosis.

John R. Bolognino * New York; Regia Università di Torino Facoltà di Medicina e Chirurgia, Italy, 1905; aged 59; died, October 22, of coronary thrombosis.

Eugene Young Amerson, Roscoe, Texas; University of Texas Faculty of Medicine, Galveston, 1939; aged 25; was killed, October 6, in an automobile accident.

Herman George Rosenblum * Flint, Mich.; Toledo Medical College, 1913; served during the World War; aged 51; died, October 28, of myocarditis.

William S. Love, Wilber, Neb. (licensed in Nebraska in 1892); aged 90; died, September 30, in St. Elizabeth's Hospital, Lincoln, of arteriosclerosis.

William Park Myers, Anaheim, Calif.; Medical College of Ohio, Cincinnati, 1899 and 1906; aged 63; died, October 1, of hypertensive heart disease.

Louis William Eckels Jr., Louisville, Ky.; Kentucky University Medical Department, Louisville, 1906; aged 55; died, October 29, of pneumonia.

Arthur William West, San Antonio, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1919; aged 53; died, October 3.

Henry Michell De Werth, North Olmsted, Ohio; Cleveland Homeopathic Medical College, 1906; aged 60; died, October 21, of heart disease.

Orlando A. Hall, Webster City, Iowa; Eclectic Medical Institute, Cincinnati, 1876; aged 92; died, August 26, of cardiac vascular disease.

Cawood Johnson Carmichael * Knoxville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1902; aged 61; died, October 9.

Charles Henry Beadles, Oglesby, Ill.; Rush Medical College, Chicago, 1890; aged 73; died, October 2, in the Peoples Hospital, Peru.

John Ephraim Elliott, Toronto, Ont., Canada; Victoria University Medical Department, Coburg, 1884; aged 81; died, September 27.

Charles G. Main, St. John, N. B., Canada; McGill University Faculty of Medicine, Montreal, Que., 1891; aged 75; died, September 7.

James Holmes Barr, Yuba City, Calif.; Chicago Medical College, 1890; formerly county health officer; aged 82; died, September 9.

Alexander Jardine Hunter, Teulon, Man., Canada; University of Toronto Faculty of Medicine, 1895; aged 72; died, August 25.

James G. Pou, Courtland, Miss.; University of Louisiana Medical Department, New Orleans, 1871; aged 91; died, September 16.

Mary Gamble Bryson, La Jolla, Calif.; Trinity Medical College, Toronto, Ont., Canada, 1903; aged 66; died, September 4.

Hyuk Chong Liu * Honolulu, Hawaii; College of Medical Evangelists, Los Angeles, 1922; aged 47; died, September 23.

Julia M. Walton, Jackson, Mich. (licensed in Michigan in 1900); aged 93; died, September 15, of cerebral hemorrhage.

Donald McKay, Collingwood, Ont., Canada; University of Toronto Faculty of Medicine, 1889; aged 74; died, September 28.

G. E. Bigham, Ivey, Ga.; University of the South Medical Department, Sewanee, Tenn., 1898; aged 65; died, September 25.

Cornelius Herman Van Ravenswaay * Boonville, Mo. (licensed in Missouri in 1897); aged 69; died, September 29.

Lemuel Allen Carter, Bunnell, Fla.; Atlanta (Ga.) College of Physicians and Surgeons, 1909; aged 52; died, September 28.

Jacob Henry Siegel, Staten Island, N. Y.; Long Island College Hospital, Brooklyn, 1908; aged 57; died, October 24.

Alexander Moir, Hensall, Ont., Canada; Manitoba Medical College, Winnipeg, 1906; aged 66; died, September 12.

Franklin Beyersdorf, St. Helena, Calif.; Missouri Medical College, St. Louis, 1879; aged 87; died, September 13.

Frederick A. Luce, Cicero, Ill.; College of Physicians and Surgeons of Chicago, 1892; aged 84; died, October 2.

David Harold Karp, Rumson, N. J.; Long Island College Hospital, Brooklyn, 1908; aged 56; died, October 12.

John Nathan Thresh, Grand Bay, Ala.; Barnes Medical College, St. Louis, 1902; aged 66; died, October 14.

Correspondence

CLOSED METHOD OF TREATING COMPOUND FRACTURES

To the Editor:—I have just read with much interest the communication (THE JOURNAL, November 23, p. 1821) of Dr. De Groat of Detroit. All his references to the history of wound treatment are correct, but his account is still incomplete. In several of my contributions, going back to 1923, I have referred to the work of Ollier (1830-1900) in bone and joint surgery. As to wound treatment, actually he made no contribution whatever. All his suggestions about wound treatment had been anticipated by Magati (1579-1647) in Italy, Belloste (1654-1730) in France, John Hunter (1728-1793) in England and others.

The editorial in THE JOURNAL to which Dr. De Groat refers, and others relating to my work on the treatment of osteomyelitis, compound fractures and infected wounds, have to do not only with the treatment of wounds and fractures by infrequent dressings but with an entire program of preliminary immobilization, drainage operation, adequate immobilization in plaster of paris casts and infrequent dressings in the postoperative care. It is extremely important that this entire program be kept in mind, as the infrequent dressing method alone, while valuable in itself, is only a part of the program necessary for best results in cases of compound fracture.

In a recent discussion led by my associate Dr. Fritz Teal before the Boston Orthopedic Club (November 18) one of the members of the audience, Dr. Otto Herman, raised, among others, the following questions:

Q.—Do you ever have to do secondary wound suturing?

A.—We do no wound suturing in any case. The closing of contaminated pockets in any wound not only interferes with drainage but affords an opportunity in some cases for the development of anaerobic infections (gas gangrene, tetanus, and the like).

Q.—Does this Orr method stimulate granulation over bare bone areas (areas laid bare by injury)?

A.—In the early reduction, indirect skeletal fixation (or direct fixation in some cases) and infrequent dressing method that we employ, all these wounds heal from the bottom, as well as from the edges, by granulation. There are no pockets at all in the best cases and, while sinuses must occasionally be reopened, we almost never have to treat the wound by closure, skin graft or otherwise.

Q.—How do you treat compound fracture dislocation about joints?

A.—Such injuries are treated by immediate reduction, enlargement of wounds for drainage if necessary, petrolatum packs (into the wound but not into the joints), pins through adjacent bones and fixation of the limb in a cast.

Q.—Do you get infection at wire fixation points?

A.—We use rigid pins fixed in plaster of paris casts and have no irritation or infection either in the bone or in the skin.

Finally, our healed (or cured) cases have always constituted between 85 and 90 per cent of all our cases. The larger death and amputation rates in most reports are due usually to shock, to postoperative mixed infections due to dressings or to gas gangrene, most of which we avoid by the program I have proposed.

These questions indicate that even by such competent surgeons as Dr. Otto Herman, some of the points in my program (since 1923) are not fully appreciated. Obviously this is the case with Dr. De Groat. There is no reason whatever for associating Ollier's name with the infrequent dressing method. Many others have suggested that. The program which I propose, however, must be considered as a whole. It is different from any other treatment ever proposed for compound fractures, osteomyelitis and infected wounds in general.

H. WINNETT ORR, M.D., Lincoln, Neb.

To the Editor:—Dr. Albert De Groat suggests in a communication published in THE JOURNAL, Nov. 23, 1940, apropos of the editorial (THE JOURNAL, September 21, p. 1022) under the heading "Closed Method of Treating Compound Fractures and Infected Wounds," that the credit for the method belongs to Ollier of Lyons and should be referred to as "Ollier's method." The originator of the method was not Ollier but Alphonse Guérin.

He invented in the pre-Lister era the method of packing the wound thoroughly with cotton and bandaging it in a circular fashion sufficiently tight so as practically to accomplish immobilization. These bandages were left undisturbed for from twenty to twenty-five days. Guérin practiced this method on a wide scale at the Hôpital Saint Louis and accomplished a rate of recoveries truly miraculous for that period. Ollier introduced important modifications into the method of Guérin. Thus he sutured the stump after amputation and applied the cotton dressing above. He also applied Guérin's method in compound fractures with displacement of the fragments. In support of my statement I submit the following bibliographic references:

GEORGE HALPERIN, M.D., Chicago.

PROSTIGMINE OF NO VALUE AS PREGNANCY TEST

To the Editor:—I wish to report my limited experience on the use of prostigmine in delayed menstruation. My results are not as favorable as those reported in the article of Soskin, Wachtel and Hechter in THE JOURNAL, May 25, on "Treatment of Delayed Menstruation with Prostigmine: A Therapeutic Test for Pregnancy."

Stimulated by the fine reports in the aforementioned article and the promotion of prostigmine methylsulfate by Hoffmann-

Results with Prostigmine Methylsulfate

Case	Friedman Urine Test	Prostigmine Methylsulfate, Ampules	Estradiol Benzoate, 2,000 Rat Units
1. V. N. aged 27; 14 days delayed; secundipara	Positive	3 x 2 cc. negative	No effect with daily doses
2. M. B. aged 22; 21 days delayed; primipara	Negative	Positive flow in 48 hrs. 2 cc.-2 cc.
3. S. A. aged 24; 5 days delayed; secundipara	Negative	Negative 3 x 2 cc.	Positive flow after 4 x dully dose
4. D. D. aged 21; 9 days delayed; secundipara *	Negative	Negative 1 cc.-2 cc.-1 cc.	Not tried

* Patient clinically pregnant after a few weeks and is observed pending delivery.

LaRoche, I decided to use the test on a small number of private patients. The 4 cases tabulated give sufficient indication that their conclusions in only a small series of 25 cases are incorrect. Four interesting variations occurred, tending to indicate that prostigmine cannot be relied on as a test in a presenting case for diagnosis. The authors' statement "If she fails to menstruate, pregnancy may be diagnosed with the same degree of accuracy as in the Friedman test" is not true.

In my first and second cases the results were confirming. My first patient gave a positive reaction to the Friedman test, with no response to prostigmine. The second had normal urine, and menstruation was produced with prostigmine. The results of the third and fourth cases disagreed. The third patient had normal urine which did not respond to prostigmine but did to estradiol benzoate. (The use of the latter I shall immediately explain). The fourth patient gave a negative reaction to a pregnancy urine test and no response to prostigmine but was found

to be pregnant clinically in a later examination. You will note four possible variations.

It will be noted that I used estradiol benzoate and it produced flow in a negative case and none in a positive one. I offer it as a suggestion in amenorrhea with a negative Friedman test. The technic I used was one ampule of 2,000 rat units daily for five doses. The flow will come during the injections or about two to four days after the last injection. How effective this treatment is I have not evaluated statistically.

ALEXANDER WINTER, M.D., New York.

"ILLUSTRATIVE ELECTROCARDIOGRAPHY"

To the Editor:—Some of the statements made by the reviewer of the book "Illustrative Electrocardiography" (THE JOURNAL, Sept. 21, 1940) are misleading. Some of the review presents debatable points on which I feel, on good authority, that our conclusions are much less theoretical and more logical than those of the reviewer.

The reviewer's criticism said: "It is questionable whether the attempt to locate the origin of the premature systole as stated on page 49 is correct." The great majority of recognized cardiologists agree with our interpretation (Nomenclature and Criteria for Diagnosis of Heart Disease, ed. 4, p. 128).

The review said: "It is doubtful whether the slight variation in the PR interval in plate 44 is worth mentioning." The variation is 0.02 second. This is certainly worth mentioning, as 0.02 second often means the difference between a normal record and a conduction block.

The review said: "The interpretation of plate 54 is wrong." Our conclusions were based on a comparison of records taken on a healthy young intern before and immediately following heavy exercise. The T wave prior to exercise was much smaller.

The reviewer said: "No useful purpose is served in showing the original lead 4 in plate 96, since this lead is no longer utilized." This is a misstatement of fact which no serious student of electrocardiography would uphold. True, the lead as such is no longer utilized, but, as the text explains, "A tremendous mass of literature has been published using the original fourth lead." Also a tremendous number of original fourth leads have been taken clinically. Furthermore, some of our noted authorities on the subject have incorporated the original fourth lead in their works and books. Both the research man and the clinician must know the basic picture from which precordial leads have evolved in order to evaluate properly the records of that time.

JULIUS BURSTEIN, M.D., New York.

CRYSTALLIZATION (?) OF METALS

To the Editor:—My attention has been called to a medicolegal abstract ("Malpractice: Liability for Injury to Patient from Nurse's Operation of Fluoroscope") in THE JOURNAL, September 28.

The National Bureau of Standards letter circular LC486, "Metals Do Not 'Crystallize' Under Vibration," has been prepared to answer the many inquiries we receive on this subject.

Members of the staff of the National Bureau of Standards are called on to examine many instances of fatigue failure in all sorts of structures. It is our experience that one fatigue failure in a certain part in a given structure which has been in use for a considerable time is all too likely to be followed by a number of like failures in the same part in other structures of the same kind which have given as long or longer similar service.

This likelihood is so great that it is frequently thought advisable in the case of a serious fatigue failure in one airplane to ground all airplanes of the same kind until they can

be examined to make absolutely sure that there is no cause to anticipate other failures of the same kind or, if cause is found, to remove it.

A roentgen ray examination is useless, since fatigue failures are not caused by crystallization.

The examination consists in looking for such surface defects as are mentioned in the letter circular, corrosion pits or craters, notches, abrupt changes in section, sharp reentrant angles, rough machined surfaces and the like, and in addition careful inspection for any fatigue cracks which may have started. For steel parts an inspection by means of divided magnetic particles, either as a dust or suspended oil (commercially known as Magnaflux), is now routine practice when fatigue cracks are feared.

If, as is implied in the report of this case, the failure was a fatigue failure, and serious personal injuries might result from like failures in other fluoroscopic tables of the same kind, it would seem to me very desirable that all tables of that particular model and other models having the same mechanical design should be carefully examined as just outlined.

If a second accident of the same kind should occur, it would seem to me, in view of this previous failure, difficult to maintain that the maker and users of the apparatus had exercised proper care to prevent it.

L. B. TUCKERMAN, Washington, D. C.
Assistant Chief, Mechanics and Sound Division,
National Bureau of Standards.

[COMMENT.—The medicolegal abstract that prompted this correspondence involved liability for injuries sustained by a patient because of the failure of a fluoroscopic table to operate properly. A representative of the manufacturer of the table investigated the accident and testified in court that a broken pin was the causal factor and further that the "parts showed it was broken from crystallization." Among other contentions the plaintiff urged that the defendants had not from time to time caused the gear box to be taken off, the gears to be removed or the pin to be taken out of its socket and placed under roentgen rays to determine whether crystallization had occurred. For further details with respect to this case readers are referred to the abstract of it, which was published in THE JOURNAL, September 28, page 1128.—ED.]

DEATH OF DR. R. FORTESCUE FOX

To the Editor:—Your London staff correspondent in his letter of August 11 (THE JOURNAL, September 21) ends with mention of the recent death of England's leading balneologist, Dr. Robert Fortescue Fox. Unfortunately, he mixed the latter's fine life record with that of a relative, Dr. Richard Hingston Fox, noted in another special field of practice.

Fortescue Fox was one of Britain's pathfinders in physical medicine, his manual on "Physical Remedies for Disabled Soldiers," to refer to only one of his authoritative writings, proving of great help to those of us stationed in hospitals during the first world war.

The concluding statement of your overseas correspondent, "A great pioneer of physical therapy, he experienced much of the disappointment of the reformer in a world which will not share his enthusiasms," may apply to conservative England but no longer to North America. Over here, aided by the American Medical Association, our profession grows ever more aware of the usefulness of modern physical treatment methods.

In later years the activities of Fortescue Fox were largely directed to thalassotherapy and balneotherapy, his editorial charge of the *Archives of Hydrology* bringing him in touch with physicians of many countries interested in spa treatment and, especially, rheumatic conditions.

Long acquaintance and admiration for the many sided talents of this leader in our profession is my warrant for this brief tribute.

A. BERN HIRSH, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

FIRE AND EXPLOSIVE HAZARD IN PRESENCE OF OXYGEN ADMINISTRATION

To the Editor:—I recently gave an order at the hospital for continuous steam inhalation and oxygen administration by catheter. The sister on duty told me that doctors in another hospital had forbidden her to administer oxygen and steam inhalation in the room at the same time. She also said that persons visiting patients receiving oxygen were not permitted to smoke. Is there any reason for such a rule? Is there any danger of explosion when a person smokes in the same room in which oxygen is being administered? If there are any contraindications to these various procedures please tell me about them and also the mechanism involved.

V. V. Anderson, M.D., Del Norte, Colo.

ANSWER.—The 20 per cent oxygen in atmospheric air is responsible for the burning of all fuels and other oxidizable substances. As the percentage of oxygen is increased, the ease with which combustion occurs increases rapidly, while the degree of heat necessary for ignition becomes less. Oxygen itself does not burn or explode from contact with a source of heat. Although a glowing heat source is necessary to ignite some materials (sheets, blankets and the like) even in high oxygen atmospheres, some substances (such as lint or organic dusts) may burn or even explode in the presence of high oxygen concentrations when exposed to moderate degrees of heat. In particular ether, vinethene, cyclopropane and ether, exhaled by the patient in the hours immediately after operation, are a great danger.

Steam is usually produced by stoves or electrical heating elements. Such sources of heat should be banned from the room of a patient receiving any form of oxygen therapy. Simultaneous administration of oxygen and steam is not harmful of itself, provided the source of heat for the latter is remote. Steam from a radiator or stem pipe or jugs of hot water is quite safe.

Smoking must be prohibited in the room where oxygen is being administered. The glowing pipe, cigar or cigaret might suddenly flare into violent flame if brought close to the patient or if air currents carried excess oxygen toward the smoker.

VACCINE VIRUS AND IMMUNITY TO POLIOMYELITIS

To the Editor:—Is there any experimental evidence or are there statistical data that vaccinia confers any immunity against infantile paralysis? Such a phenomenon seems possible to me. Vaccinia causes immunity to variola and to herpes virus. Moreover, mouse infantile virus protects monkeys against lethal doses of monkey virus. Might not extensive smallpox vaccination be worth trying as a protective measure in an epidemic of infantile paralysis?

Richard E. Stifel, M.D., Cleveland.

ANSWER.—There is no evidence that the vaccine virus confers immunity against poliomyelitis. This subject has been investigated on several occasions. In the early years, soon after the discovery of and isolation of the virus (Thompson, O.: *Berl. klin. Wchnschr.* 49:63, 1912, 51:309, 1914; *Ztschr. f. Immunitätsforsch.* 14:198, 1912), neither immunity nor alterations in the course of experimental disease were produced when the virus of vaccinia and the poliomyelitis virus were applied together on the skin. Thompson believed, however, that the poliomyelitis virus proliferated in the pustules. Hurst and Fairbrother (*Brit. J. Exper. Path.* 12:17, 1931) also concluded that the neurovaccine had no power to modify the poliomyelitis lesions in the nervous system regardless of the route of inoculation. It is known that school children who are still active in their immunity against vaccinia are just as susceptible to attacks of poliomyelitis as are children not vaccinated. These data were obtained in the Chicago and Illinois epidemics of 1936 and 1937. The status of the new cotton rat virus (Armstrong and Jungeblut) as an immunizing agent against the monkey virus has not been determined conclusively as yet.

In summary, there is no evidence that vaccination against smallpox leads to protection in an epidemic of infantile paralysis. The only positive ray of hope in protection against this disease appears to come from the recent work showing that the virus is contained in sewage and intestinal discharges of

carriers and active cases, including both paralytic and nonparalytic types. This would indicate the usual precautions which are used in the prevention of wholesale dissemination of intestinal borne diseases, including boiling of water and the prevention of congregations of children where an aqueous medium may disseminate the disease, such as swimming pools. Chlorination and other chemicals appear to have little effect on the virus.

HEREDITARY DYSTROPHY OF HAIR AND NAILS

To the Editor:—I wish to inquire about nonsyphilitic baldness showing for three direct generations. There is scarcely a trace of hair and only rudimentary finger and toe nails. 1. How often is this found? 2. What may be the cause? 3. Are such individuals usually normal physically and mentally? 4. Is it similar to albinism? 5. Kindly give the history of this condition.

M.D., Iowa.

ANSWER.—1. Cases of this type are rare and should therefore be studied and accurately recorded. The heredity should be worked out as clearly as possible, the condition of the hair, nails, teeth, skin and eyes carefully noted, and a general examination of the patient for any indications of metabolic or endocrine anomalies should be made.

2. Consanguinity of the parents has been recorded in several instances and of course this adds to the probability of the occurrence of this defect in the children. Many cases have no such easy explanation and in some the case recorded is the only one in the family, so far as known. Henry Joachim (*Dystrophy of the Hair and Nails in Six Generations, Ann. Int. Med.* 10:400 [Sept.] 1936) reports this dystrophy in nineteen of forty-two individuals in six generations of a family. In one of his cases there had been defective vision since childhood but the eye clinic reported only that the visual field of the left eye was contracted. One authority states that the partial types are of dominant heredity, while another holds that the generalized type is recessive. This is one of the reasons for urging the study of all such cases.

Besides the involvement of the teeth and nails, so common an accompaniment of alopecia congenita, eye defects, webbing of the fingers and toes, atrophy of parts of the skin, epidermolysis bullosa and alopecia areata have been recorded. J. N. Hyde, early among American writers on this condition (*Congenital Alopecia as an Expression of Atavism, J. Cutan. Dis.* 27:1, 1909), cited cases in his own practice, one of webbed fingers and toes and another of opaque patches in the retina. He also mentioned Eschner's case with exaggerated myopia and white areas in the retina. Jäckli (Ein Fall von infantiler Poikiloderma, [Atrophodermia Reticularis cum Incontinentia Pigmenti] kombiniert mit Alopecie, Mikrodentie und frühseiger Cataracta Complicata, *Monatschr. f. Kinderh.* 78:73 [March 24] 1939) reports a case of severe atrophy of the skin and bilateral juvenile cataract in a little girl whose hair, normal at birth, fell out before she was 3 weeks old and never regrew. One of Hyde's patients had xeroderma, and he mentions this complication in the case of Guilford and Luce. He also mentions Wende's case with atrophy of the finger tips and congenital epidermolysis bullosa.

3. All authorities agree that these patients show mental and physical defects, other than those mentioned in connection with the baldness, no more frequently than individuals without the ectodermal dystrophies.

4. The only similarity between this group of ectodermal defects and albinism is that both are hereditary. Albinism is a defective formation of pigment in the skin, iris and hair, often accompanied by mental and physical weakness. There is no other abnormality of the skin, hair, nails or teeth; thus albinism differs sharply from the condition mentioned in the query.

5. By "the history of this condition" it is inferred that the prognosis is meant. The best way to answer this question is to get a biopsy of the scalp. If only the merest traces of hair follicles are found, as recorded by some investigators for their cases, no hope can be given that hair will grow later. If, however, many bed hairs are seen, there is a possibility that the hair can be restored. Every encouragement should be given the patient to continue for a long time the use of local stimulants to the scalp such as are used for other types of alopecia. Ultraviolet rays in erythema doses given once or twice a week, depending on the amount of irritation caused, are an excellent stimulant; but the acquired resistance soon makes it necessary to give long treatments. Then chemical irritants may succeed it; a mixture of equal parts of tincture of iodine, chloral hydrate and phenol can be painted on once a week. One part of phenol with four parts of lactic acid is also effective. Solutions of cresol in alcohol can be used in increasing strength, beginning

with 25 per cent and going to 90 per cent. Chrysarobin in varying strength is also recommended; but great care must be exercised that none of the preparation gets into the eyes. It is well not to use these irritants at once over the whole scalp but to try out their effect first on a small area. During intervals of rest from the strong treatment milder stimulants may be used, salicylic acid and sulfur in ointment, mercurials in ointment or alcoholic solution.

COMBINED FEVER AND ROENTGEN THERAPY FOR CANCER

To the Editor:—I understand that some work is being done on carcinoma at Rochester, N. Y., with the use of high voltage roentgen therapy combined with a special type of short wave therapy. Can you furnish me with any information about this?

A. L. Goldwyn, M.D., South Ozone Park, N. Y.

ANSWER.—Studies on the combined effects of high voltage roentgen therapy and artificial fever on carcinoma are under way at Rochester, N. Y., and probably elsewhere too.

The summative effects of the two radiations x-rays and heat appear to be more destructive to the carcinoma and normal structures than either alone. Since the dosage values are not well understood the experiments have been restricted to hopeless cases. The delayed effects (telangiectases, edema, cutaneous degeneration, and the like) seem to be more marked, probably because of the summative effect.

The following dosage has been used with safety, though it should not be attempted by any one not well versed in both irradiation technic and fever treatment technic: Daily for six days 250 roentgens is given in the usual manner for any one port. On the third day in this schedule a five hour fever bout at 41.5 C. (106.7 F., rectal temperature) is administered and at the end of the fever, while the body temperature is up, that day's x-ray treatment is given. A second fever bout of one hour (or more if the patient is not too much intoxicated by the tumor destruction) is given on the fifth day with the x-ray treatment again administered at its end. Several portals may be treated simultaneously except that great caution must be exercised not to overtreat (i. e. not over 1,800 roentgens given to any one skin area) within a given course. Courses have been repeated in six months without catastrophe, although the damage to the skin was considerable.

At present this method is purely experimental and is not advocated for general use until its merits are more clearly defined.

MINERAL METABOLISM AND ELECTROLYTE BALANCE

To the Editor:—I am interested in the relation of mineral salt metabolism or, let me say, electrolyte metabolism and disease. As a matter of routine in medical conditions I elicit a dietary history from my patients and I find that the incidence of faulty eating and the preparation of foods is appalling. I should therefore like to know if any reports have been published on investigative work giving this relationship quantitatively and qualitatively. In the literature there is often mentioned the term "electrolyte pattern." Just exactly what is meant by that term? References on this most interesting subject will be greatly appreciated.

B. C. Baron, M.D., Munising, Mich.

ANSWER.—The best outline of this subject is probably to be found in the recently published monograph by A. T. Shohl on "Mineral Metabolism" (published by the Reinhold Publishing Corporation), reviewed in THE JOURNAL, April 27, page 1691. The phrase "electrolyte pattern" is subject to considerable individual interpretation. However, in general it refers to the complex interrelations of the ions of electrolytes such as the direct relation between sodium and chlorine in the tissues and the inverse relation of sodium and potassium. A good discussion for the interested physician may be found in an article by A. M. Butler on "Electrolyte and Water Balance" (*New England J. Med.* 220:827 [May 18] 1939).

COAL OIL INSTILLATIONS FOR ULCERATIVE COLITIS

To the Editor:—Has the use of coal oil by instillation in chronic ulcerative colitis been tried in competent hands? If so what quantity is used and what results have been obtained?

M.D., California.

ANSWER.—From twelve to fifteen years ago coal oil instillations into the rectum received intensive trial in cases of amebic dysentery. At the time this was used in the treatment of amebiasis and amebic colitis it was also employed in other types of chronic ulcerative colitis. It was found to be too irritating and was soon abandoned as having no great value and possibly associated with some hazard. Coal oil is irritating to the skin and so when it was being instilled it was found necessary to grease the parts about the rectum with petrolatum. The amount instilled was about a pint. Injections were given every second day for a period of twenty-eight days.

POSSIBLE ARSENIC IN MILK AND ABORTION

To the Editor:—What form of arsenic preparation is used for spraying weeds and grass? If cattle should eat the grass which has been sprayed with an arsenic preparation would arsenic be found in the cow's milk in sufficient quantity to cause an acute poisoning with severe diarrhea and a miscarriage in a woman about four months pregnant? A woman claims that such a case has occurred. The cows that ate this sprayed grass died. The cows were milked a few hours after eating the grass and the woman drank this milk. A few hours later she had severe diarrhea and abdominal cramps. She was about four months pregnant. She miscarried and has been in poor health since.

Bernard Patrick, M.D., Corinth, Miss.

ANSWER.—There are several forms of arsenic for spraying weeds and grass—sodium arsenate, sodium arsenite, calcium arsenate and lead arsenate. In the South large amounts of calcium arsenate are used, particularly on cotton fields. There is no indication in this query what form of arsenic was used. If arsenic is eaten, some of it may appear in the milk so that it is possible that some arsenic could be obtained in this way and arsenic may produce diarrhea and cramps. That this diarrhea might produce an abortion is possible, but without further evidence on the subject one cannot say more than that it is possible.

ALCOHOL BY WEIGHT AND BY VOLUME

To the Editor:—In recent months there have been frequent references to 70 per cent alcohol by weight and the greater effectiveness of this concentration as an antiseptic. What would be the volumetric equivalent of this concentration?

M.D., Illinois.

ANSWER.—There can be no constant volumetric equivalent for 70 per cent alcohol by weight unless three variables are controlled:

1. Temperature. Alcohol is so expansible that 70 Gm. of it when warm occupies a larger volume than the same 70 Gm. when cool; water, on the other hand, has a relatively low coefficient of temperature expansion. Consequently 70 per cent by weight (that is, 70 Gm. of alcohol plus 30 Gm. of water) at 15 C. is equivalent to about 76.9 per cent by volume, whereas at 30 C. it is equivalent to about 82.5 per cent by volume.

2. Reaction contraction. When alcohol and water are combined, the resultant solution contracts with production of heat and the total volume decreases further as the solution cools. Hence it makes a difference whether alcohol and water are both measured separately before mixing or whether only the alcohol is measured and water is added to bring the total volume up to a certain level.

3. Alcohol content of commercial alcohol. Different lots of commercial alcohol have been found to vary between 95 and less than 92 per cent by volume.

If these three variables are not appreciated and controlled, it is possible that the volume per cent equivalent of "70 per cent alcohol by weight" may lie anywhere between 75 and 84. Or, to put it another way, 76.9 per cent by volume (or any other set figure) as ordinarily prepared may miss by a considerable margin being 70 per cent by weight. The reason for the discrepancy is that alcohol solutions by weight are unaffected by these variables and therefore are absolutely uniform. A somewhat fuller discussion of this matter is contained in an article entitled Ethyl Alcohol as a Germicide, by Dr. Philip B. Price, in the *Archives of Surgery* 38:528 (March) 1939.

HOT FOODS AND GASTROINTESTINAL CANCER

To the Editor:—Is there any method of preventing cancer of the stomach and bowels? Are too hot drinks and food a factor in causing it?

M.D., Pennsylvania.

ANSWER.—There is no known method of preventing cancer of the stomach and intestine. Hot foods have been suspected as having an etiologic relationship to cancer of the stomach but there is no positive evidence to prove this relationship. Many observers believe that hot and irritating foods constitute one factor in the development of gastric cancer but the relative importance of this factor is not definitely known.

TESTS FOR HOMOSEXUAL TENDENCIES

To the Editor:—In The Journal of September 28, 1940, on page 1122, I notice a reply to an inquiry about possible homosexual tendencies. I should like to suggest in addition to the routine psychiatric examinations and textbooks that are recommended the utilization of projective tests. Examination by means of the Rorschach test and the Szondi test could easily give much more complete and adequate information than any formal psychiatric examination could yield—that is, provided the tests are given by some person fully qualified to administer and interpret them.

Milton H. Erickson, M.D., Eloise, Mich.

Medical Examinations and Licensure

COMING EXAMINATIONS

BOARDS OF MEDICAL EXAMINERS

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examination of boards of medical examiners and boards of examiners in the basic sciences were published in *THE JOURNAL*, December 7, page 2019.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, February 10-12. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*. Various centers, Feb. 20. Final date for filing application is December 21. *Oral*. Part II. Cleveland, May 31-June 1. Final date for filing application is April 1. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. Parts I-A and I-B, Feb. 17. Final date for filing application is Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Part II, Groups A and B, Cleveland, May 28-June 1. Final date for filing application is March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. Cleveland, May or June. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF PATHOLOGY: *Oral and Written*. Cleveland, June 1-2. Final date for filing application is May 1. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: New York, March 30-31, following the Region I meeting of the American Academy of Pediatrics. Chicago, May 18, following the Region III meeting of the American Academy of Pediatrics. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF RADIOLOGY: *Oral*. Cleveland, May 30-June 1. Final date for filing application is April 15. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

Indiana June Report

Dr. J. W. Bowers, secretary, Indiana State Board of Medical Registration and Examination, reports the written examination for medical licensure held at Indianapolis, June 18-20, 1940. The examination covered fifteen subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and eighteen candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
College of Medical Evangelists.....	(1940)		1
Yale University School of Medicine.....	(1939)		1
Loyola University School of Medicine.....	(1940, 3)		3

Book Notices

Graduate Medical Education. Report of the Commission on Graduate Medical Education. Cloth. Pp. 304. Chicago: University of Chicago Press, 1940.

The Commission on Graduate Medical Education was organized in 1937 as an offshoot of the Advisory Board for Medical Specialties, which felt that it was more representative of the different interests involved than any other body. The commission's activities were financed by the Rockefeller Foundation, the Carnegie Foundation, the Josiah Macy Jr. Foundation and some smaller contributions from other groups. Concerning internship it concludes:

1. The internship should be regarded as a part of the basic preparation for either beginning the general practice of medicine or undertaking advanced training in a specialty.
2. The internship should provide a real educational experience and a period of clinical responsibility under supervision that is designed to complete the clinical clerkship of the medical course.
3. The internship should be an important responsibility of the staff and should be under the direction of those members who are competent to provide the necessary instruction.
4. The internship should be a joint responsibility of the medical schools and of those hospitals that can provide a satisfactory completion of the fundamental preparation for medical practice.

Of residencies it says:

1. The residency should be the most satisfactory method of graduate training for specialized fields of practice.
2. The residency should be organized as a real educational experience provided by qualified teachers who are willing to assume responsibility for adequate instruction.
3. The residency should provide preparation in the sciences basic to the specialty as well as sufficient clinical experience, under supervision, to ensure real competence.
4. The residency should be a joint responsibility of medical schools and of those hospitals able to provide residencies of a satisfactory educational character.

The following are stated to be the basic principles of postgraduate medical education:

1. Postgraduate medical education should aim to keep the physician abreast of current knowledge in his present field of practice.
2. Postgraduate medical education, as defined in this report, should not attempt to qualify a physician for entering a specialized field of practice.
3. Postgraduate medical education divides itself into two independent categories which should be clearly differentiated; namely,
 - (a) Instruction for general practitioners.
 - (b) Instruction for those who are already qualified as specialists.
4. Postgraduate medical education should be offered only by those who are qualified to provide satisfactory instruction.
5. Postgraduate medical education should be coordinated by existing agencies in each state that are concerned with the health and medical care of the population.

This report has been criticized primarily because of its point of view. It has been charged that it represents a concept that the family doctor is merely an agent to direct his patient to a specialist. Today most of the physicians of the United States are in general practice. Unfortunately that very fact makes them less prominent in the groups of physicians who concern themselves with committees, councils and similar bodies that spend much of their time in discussions of medical education. The *Journal of the Michigan State Medical Society* has urged that a commission of general practitioners be organized to establish their point of view as to the principles which should underlie the training of interns. Some hospitals are beginning to recognize the validity of this criticism by the appointment of general practitioners to membership on their staffs and also by the establishment of residencies in general practice. Graduate medical education is still in what might be called an early experimental stage. Fortunately, this fact is recognized by most of the bodies which are concerned in the field and even the standards set by the certifying boards are not yet to be considered as the ultimate in each of these fields. The contribution of the Commission on Graduate Medical Education may be classified as "work in progress." The conditions change so rapidly that most of the tabular data which make up the appendix are already obsolete.

Allergiya i desensibilizatsiya. Pod redaktsiyei D. E. Alperna. L'allergie et la désensibilisation. Cloth. Price, 11 rubles. Pp. 217, with illustrations. Kharkov: Izdanie Ukrainskogo Instituta Eksperimental'nogo Meditsiny, 1940.

This small volume, published by the Ukrainian Institute of Experimental Medicine, contains brief reports on experimental and clinical studies in allergy and desensitization by Prof. D. E. Alpern and his co-workers. Alpern makes a distinction between specific and nonspecific desensitization. The first consists in creating within the organism a resistance to the antigen by immunobiologic action in the presence of antibodies. By nonspecific desensitization is meant the reduction of the exaggerated reactivity by means other than immunobiologic, namely, through the intervention of the regulatory systems of the organism, its metabolism and so on. There are chapters dealing with animal experiments and clinical trial of histamine, of ultrashort waves and of intermedin. Alpern claims to have obtained this hormone containing extract of the pars intermedia of the hypophysis long before Zondek (1932) described intermedin containing the melanotrophic hormone. He describes his method of obtaining the hormone from the hypophysis of small and large horned cattle. Several chapters are devoted to the effect of intermedin. Its effectiveness is determined by the extent to which allergy participates in a given pathologic state. The greater the allergic factor, the more effective is the intermedin. The latter was always effective in shock attending blood transfusion, in allergic disorders of the nasal mucous membranes, in phlyctenules, in recurrent rheumatism and in other allergic diseases. The work is in Russian with a synopsis in French accompanying each chapter.

Progress in Medicine: A Critical Review of the Last Hundred Years. By Iago Galdston, M.D. With a foreword by Henry E. Sigerist, M.D. Cloth. Price, \$3. Pp. 347. New York & London: Alfred A. Knopf, 1940.

Interesting himself in philosophies more than in events and personalities, the author has produced here a historical meditation concerning medical progress ostensibly only in the last century but in reality covering much more in point of time. His approach is reminiscent of Singer rather than of Clendening, Haggard or Major, whose historical essays for lay readers bid fair to become lasting contributions to this field of medical literature. He objects to "history viewed in the light of its heroes" because the lapses between the times of heroic individual achievements appear to be dark ages or voids. "History viewed as the progression of ideas has no dark ages" the author says in his introduction.

Proceeding on this theory, he opens with a review of "Preludes to Pasteur." Tracing the evolution of man's conceptions as to the causes of disease from Homer's description of the plague of the mules and the swift dogs which was ultimately communicated to man and attributed to the displeasure of Phoebus Apollo with Agamemnon, he sketches swiftly the outlines of development to the era of Pasteur, Koch and their compatriots and followers, with emphasis on the flow of thought and the growth of ideas and understanding rather than on the men through whom the ideas are implemented. As he states in his introduction "Ideas . . . do not progress by themselves. They have need for vehicles, human beings. We never confront a disembodied idea. There is always a man to express it, to cherish it, to defend it, to propagate it. In that respect ideas and human life have this in common, that each man receives his from another, to pass on, better or worse, but never to create independently."

From the pre-Pasteur era he traces the progress of medical thought through the era of those whom he calls the pasteurians, whose thinking was along microbian lines, to the challenge of nutrition problems, the rise of glandular knowledge, mental hygiene and psychiatry from Mesmer to Freud, a century of clinical progress, and a closing chapter entitled "Whither Medicine?" This is a prognosis for medicine in the scientific, not the economic, realm. The author's forecast is perhaps best represented, as far as brief quotations can represent it, in the following passages: "It is none too optimistic to believe that during our very lifetime 'some great truth has been loosened' in medicine, a truth that holds the proper precinct of medicine to be life, not death, that deems its primary concern to be health

not disease, that looks to the safeguarding of the man rather than to the conquest of the malady." However, as to the imminence of achievement of this "loosened truth" he says "The time . . . is not ripe, though medicine is, for the widespread practice of personal preventive medicine. I say medicine is ripe, but its ripeness is not full blown. Medicine today is not only adding much to its knowledge but is summing up much of what it has gathered into larger concepts and broader understanding. . . . But we do have more parts to put together." His final summation is in the words of Cicero: "Man never come closer to the gods than in giving health to men."

The book is thoughtful and thought provoking. It is not light reading, yet it is not hard reading, thanks to the author's broad acquaintance with medical and cultural literature, his individuality of style and the richness of his vocabulary. It is heartily recommendable for the physician and the thoughtful lay reader.

Textbook of Public Health. By W. M. Frazer, O.B.E., M.D., Ch.B., Medical Officer of Health, City and Port of Liverpool, and C. O. Stallybrass, M.D., Ch.B., D.P.H., Deputy Medical Officer of Health, City and Port of Liverpool. (Formerly Hope and Stallybrass.) Tenth edition. Cloth. Price, \$6.50. Pp. 504, with 64 illustrations. Baltimore: William Wood & Company, 1940.

The present edition of this standard work is thorough in all aspects of the subject and as complete a textbook on public health as the graduate student could desire. The obvious comparisons between the English and American methods are interesting, especially the section on milk production and inspection. Apparently pasteurization is not nearly as widespread a procedure in the British Isles as it is in the United States. The chapters on industrial hygiene, water, sewage disposal and housing are progressive and represent the modern trend of thought. Health officers in the United States have much to learn from the planned housing programs of Britain, and the various pages devoted to proper dwellings are of value and importance. Of additional interest is the chapter pertaining to marine hygiene, a subject that is frequently neglected in the average book on public health. The chapter on meteorology perhaps overemphasizes the effects of climate. Maternity and child welfare and school medical service are minutely described, including plans and diagrams of child welfare clinics. The absence of a separate chapter on public health nursing might be considered a defect. A departure from the usual is noted in the chapter on hospital administration, an oft neglected part of public health administration. This excellent volume closes with a chapter on medical aspects of civil air defense which is timely and well written. The book is thoroughly indexed.

Clinical Urology. By Oswald Swinney Lowesley, A.B., M.D., F.A.C.S., Director of the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital, New York, and Thomas Joseph Kirwin, M.A., M.S., M.D., Attending Surgeon of the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital. Volumes I and II. Cloth. Price, \$10, per set. Pp. 898; 899-1684, with 370 drawings by William P. Didusch. Baltimore: Williams & Wilkins Company, 1940.

In the development of this work, planned primarily for the medical student and general practitioner, the authors have followed classic arrangement by beginning with the general diagnostic procedures, including a chapter on history taking and physical examination, and then considering the organs of the urogenital tract in anatomic sequence from without inward. The first volume covers the external genitalia, with a special chapter on gonorrhea, and includes all the tissues through the prostate gland. The second volume is concerned with the bladder, the ureters and the kidneys, and there is a concluding chapter on radium and roentgen therapy of the genito-urinary tract.

Exceptional in this book are the magnificent illustrations by Didusch, of which there are a tremendous number both in black and white and in colors. Exceptional also is the readability of the type, which makes study of the book a veritable pleasure for the eye. The work is one of the most practical that is available, and the information particularly with regard to treatment is succinct and definite. The numerous side headings and center headings in various type make the acquiring of information relatively simple because the book falls naturally into excellent

outline form. So rapidly has chemotherapy developed in recent years that the book is already a little behind times as far as concerns some of the newer sulfonamide derivatives. Indeed, the book includes an extraordinary spelling of sulfathiazole. Nevertheless the volume contains references to periodical literature as late as February 1939. As a guide to the general practitioner these volumes may be recommended for their practicality and for their well considered didactic expression.

Problemy teoreticheskoy i prakticheskoy meditsiny. Leksii po usovershenstvovaniyu vrachev. Sbornik sedmoy. Otvetsstvennyy redaktor: S. Ya. Shumarov. [Problems of Theoretical and Practical Medicine. Postgraduate Lectures for Physicians. Seventh collection.] Boards. Price, 7 rubles. Pp. 272, with illustrations. Moscow: Izdatie Gosudarstvennogo Tsentralnogo Instituta Usovershenstvovaniya Vrachey, 1938.

This volume, in Russian, contains a series of lectures delivered in a ten day review course offered by the Central Postgraduate Institute. The ten day program was arranged so that each lecture presented a more or less complete review of the present status of a problem with emphasis on the contributions of Soviet medicine. The most prominent representatives of Soviet medicine were invited to participate. Preference was given to physiologic problems. On reading some of these lectures the reviewer felt that either the average Soviet doctor was head and shoulders above an average American physician or that the lectures went over their heads. They read in fact as an advanced seminar in physiology. Perusal of the titles alone is sufficient to indicate their highly theoretical nature. Thus, "The Modern Status of the Localization of Nervous Functions," "The Problem of the Center and the Periphery in the Physiology of Nervous Activity," "The Cortex and the Work of Internal Organs," "Chemical Nature of Ferments."

The Chinese Way in Medicine. By Edward H. Hume. Cloth. Price, \$2.25. Pp. 189, with 9 illustrations. Baltimore: The Johns Hopkins Press, 1940.

This book falls into three parts. The first deals with the universe and man in Chinese medicine and is a summary of the views of Chinese philosophers whose teachings afford the philosophical basis for Chinese medical procedures. These include the cosmic philosophy of Lao-tse with its two opposed forces, Yin, the negative, or female, and Yang, the positive, or male; the kwei or animal spirit, and the shen or intellectual spirit, both acquired during fetal life from the parents. Childbirth is a period of great susceptibility to spirits, and mental disturbances are due to excitement of the shen; hence exorcism by the cock, whose kinship with the sun confers on the blood of that bird subtle powers over the mind. The vegetable kingdom is also beset by spirits. The pine, cypress, peach and fungi possess the magic ling. Tao, the Way of Nature, gave rise to the belief in immortality, the Happy Islands, and indirectly to the elaborate systems of breathing, diet and physical exercises conducive to longevity. The mineral world also had its place in Chinese medicine, and gold, jade and pearls their place in medical lore. The second part is devoted to a review of the medical classics of the Chinese, in which are traced the rise of the elaborate use of the pulse in diagnosis, the development of herbals, the elaboration of anesthesia and surgical practice, and vaccination. The third part enumerates the distinctive contribution from Chinese medicine. The animistic, cosmic and medicamentous approach to disease are interesting historically but the last is most fruitful. Their empiric methods led to the use of the lining of the pig's stomach in anemia, the use of marine algae in thyroid disease, and of fish livers in scrofula and lung diseases. The use of poisonous reptiles and of the pills of eight poisons belong with that of the cicada and of jade more in the field of magic than of medicine. The important contributions are the origin of medicinal libraries and of medical monographs such as those on leprosy, venereal disease, smallpox, beriberi, obstetrics, gynecology and ophthalmology. Among medicaments of proved value used in Chinese medicine are stramonium, deer's horn (for calcium), Ephedra vulgaris, musk, iodine from seaweed, toad venom, chaulmoogra oil, tang kwei from *Cryptotaenia canadensis*, from which eumenol is derived, anthelmintics, fish oils and arsenic. Physical therapy is found in acupuncture and moxa, in the art of breathing and in physical exercises.

Mosquito Control: Practical Methods for Abatement of Disease Vectors and Pests. By William Brodbeck Herms, Sc.D., and Harold Farnsworth Gray, Dr.P.H. Cloth. Price, \$3.50. Pp. 317, with 60 illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1940.

This handy book on mosquito control is an exhaustive study of the principles underlying the problem and the actual methods of abatement. Beginning in the introduction with a brief historical sketch of the origin of control, the work continues with the brief discussion of the cost of malaria from an economic point of view. State laws are reviewed and various nonofficial agencies for mosquito abatement are described. The various methods of control are described in great detail, as is also their adaptation to various types of land to be treated. An interesting chapter written with a sense of dry humor rarely seen in scientific textbooks is that on mosquito control by use of fish. The special features of the problem in urban and rural areas are described and the problem of the mosquito in the airplane and the military phases are not neglected. Considerable emphasis is placed on the education of the public in order to maintain interest and support for the carrying on of the work. Appendixes, dealing with the distribution of the anophelines and their larval habitats and a classification of methods, together with a selected bibliography, make it an extremely handy reference book. The authors have been actively associated with mosquito control work on the west coast for thirty years and the book will serve as a valuable guide for all those engaged in any aspect of mosquito abatement.

Synopsis of the Principles of Surgery. By Jacob K. Berman, A.B., M.D., F.A.C.S., Assistant Professor of Surgery, Indiana University School of Medicine, Indianapolis. Fabrikoid. Price, \$5. Pp. 615, with 274 illustrations. St. Louis: C. V. Mosby Company, 1940.

As the title indicates, this is another synopsis of the principles of surgery. Yet this one is much different from all the others on the subject and is probably the best that has been the privilege of the reviewer to see. The essential and most valuable feature of the book is that it is written with the idea of correlating the basic sciences with the fundamental principles of surgery. This the author accomplishes in a novel manner. The body of the text contains a discussion of the standard principles of surgery which are found in almost every textbook, while in footnotes, nearly as extensive as the text itself, he covers the related and pertinent facts of anatomy, pathology, biochemistry and physiology. Though the discussions are necessarily brief, the subject matter is covered completely and well. There is a tremendous amount of information between the covers of this volume, all of which is abreast of the time. The book is written in clear, simple style. It is attractively printed and contains a large number of excellently reproduced photographs and line drawings which enhance the value of the text. The book is highly recommended for surgeons as well as students for whom it was intended.

Clinical Dental Roentgenology: Technic and Interpretation Including Roentgen Studies of the Child and Young Adult. By John Opple McCall, D.D.S., F.A.C.D., Director, the Murry and Leone Guggenheim Dental Clinic, New York, and Samuel Stanley Wald, D.D.S., F.A.C.D., Head of the Department of Diagnosis and Roentgenology, the Murry and Leone Guggenheim Dental Clinic and School for Dental Hygienists. Cloth. Price, \$5.50. Pp. 319, with 1,046 illustrations. Philadelphia & London: W. B. Saunders Company, 1940.

This book is by teachers of dentistry, intended for practicing dentists and for radiologists or other physicians interested in dental roentgenology. The pages on technic call for clarification and condensation and chapter II, on electricity and roentgenology, merits no serious consideration by readers; but the bulk of the work, which deals with diagnosis, is excellent and is recommended without reservation to physicians desirous of improving and modernizing their ability to interpret dental roentgenograms. The anatomy of the teeth and jaws at all ages from fetal to adult life is described, and certain concepts of development that have become established among orthodontists are convincingly disputed. Periapical lesions, unerupted teeth, salivary duct stones and infections, tumors and injuries of the jaws are well described and illustrated. In addition to these familiar subjects there are discussed many others not so well known to physicians, such as growth phenomena, dental caries and periodontal disease.

Miscellany

PROPOSED ADDITIONS AND DELETIONS FOR THE UNITED STATES PHARMACOPEIA

Herewith is the report of the Subcommittee on Scope of the U. S. Pharmacopeia, Twelfth Revision. It consists of (a) a list of articles not formerly described in the Pharmacopeia but now recommended for inclusion in the U. S. P. XII and (b) a list of articles official in the U. S. P. XI but not recommended for admission to U. S. P. XII (commonly spoken of as "deletions").

ARTICLES NOT FORMERLY PHARMACOPEIAL NOW RECOMMENDED FOR THE U. S. P. XII

Absorbent Gauze	Picrotoxin
Absorbent Gauze, Sterile	Picrotoxin Solution (for injection)
Adhesive Absorbent Compress	Potassii Chloridum
Antipneumococcus Serum (the new monograph to cover all types)	Quinine Hydrochloride
Calaminae Preparata	Quinine Hydrochloride with Ethyl Carbamate Solution (for injection)
Calcium Mandelate	Riboflavin
Dextrose Solution (for injection 50 per cent)	Ringer's Solution
Dextrose (50 per cent) and Sodium Chloride (30 per cent) Solution (for injection)	Serums, Dry and Liquid forms authorized for all U. S. P. Serums
Elixir Cardamomii Compositum	Surgical Silk and other Surgical Sutures
Elixir Iso-Alcoholicum	Surgical Silk and other Surgical Sutures Sterilized
Elixir Phenobarbitali	Syrupus Ammonii Mandelatis
Elixir Terpinii Hydratis	Syrupus Glycyrrhizae
Ethyl Carbamate	Syrupus Rubi Ideaei
Gas Gangrene Antitoxin (to include types now used)	Telluriae Aminopyrinae
Gauze Bandage	Tetanus Toxoid
Glycocol (Amino Acetic Acid)	Tetrachloroethylene
Immune Serum for Scarlet Fever, Human	Theobromine with Sodium Acetate
Immune Serum for Measles, Human	Totaquinine
Immune Globulin (Placenta Extract) Human	Transfusion Normal Plasma, Human
Lotio Calaminae	Transfusion Normal Syrum, Human
Lotio Calaminae Phenolata (2 per cent Phenol)	Trichloroethylene
Magnesium Trisilicate	Urea
Oleum Hippoglossi (Halibut)	Vitamins A and D in Oil (Cod Liver Oil Strength)
Oubain	Zinc Peroxide

The following additional items, needed as "pharmaceutic necessities," must be added as new admissions:

Compound Spirit of Cardamom	Raspberry Juice
Cudbear	Spirit of Bitter Almond
Oil of Caraway	Tincture of Cudbear
Oil of Cardamom	

ARTICLES OFFICIAL IN THE U. S. P. XI, BUT NOT ADMITTED TO THE U. S. P. XII, COMMONLY SPOKEN OF AS "DELETIONS"

Acetum Scillae	Merbaphenum
Acidum Aceticum Dilutum	Mistura Opii et Glycyrrhizae Composita
Acidum Acetylsalicylicum	Oleum Santali
Acidum Sulfuricum Aromaticum	Pancrreatinum
Aconitum	Paraffinum
Albumini Tannas	Pepsinum
Ammonii Benzoas	Pilocarpinae Nitras
Ammonii Bromidum	Pilulae Aloes
Ammonii Salicylas	Podophyllum
Arseni Triiodidum	Potassii Chloras
Asafoetida	Pulvis Ipecacuanhae et Opii
Bismuthi Subgallas	Pulvis Sennae Compositus
Calcii Bromidum	Pyrogallol
Calcii Creosotas	Quinina
Cannabis	Resina Podophylli
Cantharis	Santoninum
Capsicum	Scilla
Carbo Activatus	Serpentaria
Carbromalum	Sodii Acetas
Ceratum Cantharidis	Spiritus Aethylis Nitritis
Cinchona	Spiritus Chloroformi
Colchici Semen	Strychninae Nitras
Copaiba	Sulfonethymethanum
Creosoli Carbonas	Sulfur Lotum
Creosotum	Syrupus Ferri Iodidi
Dichloramina-T	Syrupus Scillae
Emplastrum Cantharidis	Terebentum
Emulsio Asafoetidae	Theobromina cum Sodii Salicylate
Extractum Cannabis	Tinctura Aconiti
Extractum Nucis Vomicae	Tinctura Cantharidis
Ferrum	Tinctura Capsici
Fluidextractum Belladonnae Radicis	Tinctura Cinchonae Composita
Fluidextractum Cannabis	Tinctura Colchici Seminis
Galla	Tinctura Ferri Chloridi
Guaiacol	Tinctura Kino
Hydrargyri Iodidum Flavum	Tinctura Scillae
Iodoformum	Tinctura Valerianae
Kino	Tinctura Veratri Viridis
Liquor Ammonii Acetatis	Unguentum Gallae
Liquor Ferri Chloridi	Valeriana
Liquor Ferri Tersulfatis	Veratrum Viride
Magma Ferri Hydroxidi	
Massa Hydrargyri	

Physicians are encouraged to send comments on the foregoing proposals either to the Chairman of the Pharmacopeia Revision Committee, Dr. E. Fullerton Cook, Forty-Third Street and Woodland Avenue, Philadelphia, or to the Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Basic Science Law (Arkansas): Constitutionality and Applicability to Chiropractors.—The legislature of Arkansas in 1915 enacted a statute creating a state board of chiropractic examiners and required it to examine prospective chiropractors in the subjects of anatomy, physiology, symptomatology, chemistry, hygiene, chiropractic principles and diagnosis. In 1929 a basic science law was enacted in Arkansas which requires every applicant desiring a license to practice the healing art or any branch thereof to pass an examination in the basic sciences—anatomy, physiology, chemistry, bacteriology and pathology—and present to the licensing agency a certificate to that effect, issued by the state board of examiners in the basic sciences, before he may be permitted to take a further examination for the particular branch of the healing art which he desires to pursue. This law excepted from its application dentists, nurses, midwives, optometrists, chiropodists, barbers, cosmeticians and Christian scientists. By reason of these statutory provisions, the plaintiff, the Arkansas Medical Society, petitioned the Pulaski chancery court for an injunction (1) to restrain the defendant state board of chiropractic examiners from issuing licenses to practice chiropractic to any applicants who failed to present certificates showing satisfactory completion of the required examination in the basic sciences and (2) to enjoin two individual chiropractors from practicing chiropractic under invalid licenses issued to them by the state board of chiropractic examiners without their having complied with the basic science law. From an order of the court denying the petition, the plaintiff appealed to the Supreme Court of Arkansas.

The defendants contended that the basic science law does not apply to the practice of or the licensing to practice chiropractic and that so far as it attempts to regulate such licensing or practice it constitutes an unreasonable and unconstitutional interference with the right to practice chiropractic. In support of this contention the defendants argued that bacteriology and pathology, two of the subjects in which applicants for licensure to practice the healing art are required by the basic science law to take examinations, were neither essential to nor connected with the practice of chiropractic. With this contention, however, the Supreme Court of Arkansas could not agree. The legislature, said the court, believed it proper that all persons seeking a license to practice the healing art should have a knowledge of, among other subjects, bacteriology and pathology, and we cannot say their inclusion as to chiropractic was unreasonable, arbitrary and without any relation to such practice. Bacteriology is defined by Webster as "The science which deals with the study of bacteria. It is a branch of botany, but some of its most important practical relations are with hygiene, medicine and agriculture." Certainly bacteriology has some relation to the practice of chiropractic since "some of its most important practical relations are with hygiene," a subject in which a prospective chiropractor is required by the chiropractic practice act to take an examination. Pathology is defined as "The science treating of diseases, their essential nature, causes and development, and the structural and functional changes produced by them." In reply to the defendants' argument that the subject of pathology was not related to the practice of chiropractic because chiropractors do not diagnose or treat disease but merely locate "the nerve pressure of the spinal column" and make proper adjustments to relieve that pressure, the court said: "If he does not treat diseases, what does he treat? Does he manipulate the vertebrae of a well person just for the pleasure of such well person? There would be no excuse for any regulatory chiro-

practic laws, if they were not engaged in treating disease." In the judgment of the court, the basic science law does apply to the practice of and the licensing to practice chiropractic, which is a branch of the practice of the healing art, and applicants for license must successfully pass examinations in the basic sciences before the basic science board of examiners as a prerequisite to eligibility for examination before the chiropractic board.

Furthermore, continued the court, the basic science law does not abridge the rights and privileges of chiropractors but simply places additional requirements on the qualifications for practice. It merely regulates the practice of chiropractic but does not ban it. The fact that the basic science law excepts from its operation dentists and certain others does not constitute, as the defendants claimed, an arbitrary and unreasonable classification.

The Supreme Court of Arkansas concluded that the basic science law is constitutional, and so it reversed the judgment and remanded the case with directions that the injunction be granted. An appeal to the United States Supreme Court was dismissed for want of a substantial federal question.—*Stroud et al. v. Crow et al. (Ark.)*, 136 S. W. (2d) 1025; 61 Sup. Ct. 17.

The Familial Epidemiology of Rheumatic Fever

DR. MAY G. WILSON, DR. RALPH E. WHEELER, and MORTON D. SCHWEITZER, PH.D., New York: Taking the family as the unit for epidemiologic study, the relation of environment, contagion and heredity to the spread of rheumatic fever in 112 families was considered. It was found that the frequency of rheumatic fever did not differ significantly in families of varying economic levels ranging from dire poverty to middle class comfort, although rheumatic recurrences were less frequent among children living under relatively favorable environmental conditions. No evidence was obtained that rheumatic fever is passed back and forth from case to case in the family. Simultaneous attacks in the household were no more frequent than might have been expected from chance association. The incidence of recurrences bore no direct relation to the size of family or the number of rheumatic members and seemed to represent recrudescences of existing disease rather than new infections. Unlike most acute communicable diseases, the age of onset for children presumably exposed within the family (secondary cases) was not earlier than for those exposed "outside" the family (primary cases). No evidence was obtained to indicate that a rheumatic parent or child constituted a hazard per se to the nonrheumatic or quiescent members of the family group. Two different secondary attack rates were obtained. The rate for families in which one parent was rheumatic was double that for families in which

neither parent was rheumatic and four times as great in families in which both parents were rheumatic. These observations are apparently inconsistent with a hypothesis of contagion. They do, however, afford additional evidence that hereditary susceptibility underlies the familial incidence of rheumatic fever.

DISCUSSION

DR. HELEN B. TAUSSIG, Baltimore: Our studies in Baltimore fundamentally support those of the authors. My associates and I have found that there is a high familial incidence in rheumatic fever and there is evidence of a strong hereditary factor. We too have shown that its behavior is not that of an acute communicable disease. Its development is more like that of tuberculosis than like measles. We agree entirely that the incidence of rheumatic fever is higher in families in which one or both parents has had rheumatic fever than when neither parent has had the disease. On the other hand, I do not think this can be taken as evidence that the disease is primarily due to a hereditary predisposition and not an environmental factor. That belief rests on the assumption that chronic rheumatic fever is not contagious; we have no evidence to support that view. On the contrary, the fact that most people with rheumatic heart disease die of the disease leads to the belief that infection persists for a long time and may play an important part in the spread of the disease. It is noteworthy that after introduction of an acute case of rheumatic fever the secondary attack rate doubles and increases proportionately as much in the group in which the parents have not had rheumatic fever as in the group in which the disease is present in one or both parents. This, we believe, is evidence that this is an environmental factor. We have no indication whether the environmental factor is nutritional or exposure to damp and cold, but we do believe that there is an environmental factor as well as a hereditary one.

DR. JOHN R. PAUL, New Haven, Conn.: This discussion is concerned with the nature of rheumatic fever. More knowledge of this particular aspect of this disease is what we need. Dr. Wilson and her co-workers have used a difficult technic, but it is a method which holds some promise in the study of this and other diseases. It was used with success by Dr. Opie in tracing the spread of tuberculosis through families. The advantage, as the authors expressed it, which students of tuberculous families have over those who study rheumatic fever is that in tuberculosis there are many more diagnostic aids. One difficulty with rheumatic fever families is that of trying to discover what is really going on. The results in our family studies do not differ much from those that Dr. Wilson has shown, but our conclusions are, perhaps, not quite as definite. My associates and I believe that heredity plays an important, though not necessarily a dominant, part in determining the prevalence of this disease. We believe that there seems to be adequate evidence to show that the children of rheumatic parents acquire this disease with greater frequency than do the children of nonrheumatic parents. The degree to which hereditary influences prevail in rendering the host more or less susceptible to many infectious diseases is the question. Of course there must be strong environmental influences at work, such as climate, and poor living conditions. Another example of the effect of environment in rheumatic families is the manner in which upper respiratory infections precipitate an attack of rheumatic fever. Acute epidemics of rheumatic fever occur when an acute infection invades a "rheumatic family" just as they occur when such infections invade a convalescent home.

DR. JAMES F. RINEHART, San Francisco: The authors speak of a group in which the food was adequate and a group in which it was not adequate. I should like to ask to what extent a detailed analysis of nutrition was made. I am thinking of a possible deficiency in vitamin C.

DR. T. DUCKETT JONES, Boston: I should like to ask whether the authors have had any experience with offspring of rheumatic parents, either one or both, who have lived entirely away from the environment of the parents, even in different sections of the country, and especially where rheumatic fever is not common.

DR. MAY G. WILSON, New York: The data have not all been presented because of time limitations. We had 800 calendar years of activity, of which 25 per cent were simultaneous years,

that is multiple cases of activity during the same year. This is no more than might be expected by chance. The work reported by the Johns Hopkins group on the prefamilial and postfamilial attack rate is still a subject of debate between us. In these 112 families the children were not separated, but we know of families in our clinic in which children living apart from parents had rheumatic fever. I think data might be included on children who are adopted or sent out to other homes where there are non-rheumatic parents. I have asked those engaged in adoption work to look out for it. Such data would be significant. These homes have been under long observation of our social workers who were familiar with the food served to the children. Notes were made at each home visit as to the amount and balance of food, and particularly if vitamin C was inadequate.

Cultural Studies on Rheumatoid Arthritis and Rheumatic Fever

DRS. D. MURRAY ANGEVINE, SIDNEY ROTHBARD, and RUSSELL L. CECIL, New York: The patients with rheumatoid arthritis studied were those in the active stage of the disease, that is with pain and swelling of the joints and usually an increase in the sedimentation rate. The blood cultures were taken whenever possible in a dust-free, airfiltered room. Masks were worn by the operators during all procedures, and the transfers of cultures were made with rubber bulbs on the pipets. The aerobic clot method was used for most cultures. The principal medium used was dextrose phosphate broth. Repeated subcultures were made at intervals of five days for one month. Forty-nine of sixty-one (80 per cent) blood cultures made on fifty-eight patients yielded no growth. The following organisms were obtained from twelve of the cultures: Five showed a large gram-positive diplococcus (not identified), four *Staphylococcus albus* and the others an alpha prime streptococcus, *Staphylococcus aureus* and *B. subtilis* respectively. Additional cultures were made of synovial fluid and tissue, as well as subcutaneous nodules on similar medium enriched with horse blood. Twenty-two cultures of synovial fluid from twenty patients were sterile. Five of seven cultures of synovial tissue were sterile; *Micrococcus tetragenes* was grown in one instance and *Staphylococcus albus* in one. Five of nine subcutaneous nodules were sterile, three yielded *Staphylococcus albus* and one a gram-positive diplococcus. Special cultural studies were made according to the method of Klieneberger for the presence of a pleuropneumonia-like organism in the synovial fluid, synovial tissue or subcutaneous nodules from thirteen patients with rheumatoid arthritis. In no instance was such an organism recovered. The synovial fluid, tissue, or subcutaneous nodules from sixteen patients were inoculated on the chorio-allantoic membrane of the chick embryo, 185 eggs being inoculated and thirty-five subpassages made. No significant transmissible lesion was produced. Similar material was also instilled into the nares of young white mice (strain CF 1) under light ether anesthesia. Occasionally small areas of pneumonia developed after the first instillation. Thirteen of 127 mice injected in this manner developed small, patchy areas of pneumonia following the first instillation. Several passages, usually six, of normal and pneumonic lungs were made at intervals of from four to six days. In a few instances a transmissible pneumonia developed; however, this was so irregular and inconsistent that we feel it was probably caused by a mouse virus or pleuropneumonia-like organisms. Material from seven cases of rheumatoid arthritis was injected intravenously, intracerebrally, intraperitoneally or subcutaneously into mice. No significant lesions were produced, nor was any transmissible agent recovered. Irradiated mice were used in many instances; however, no difference was found between these and the non-irradiated mice in respect to the development of pneumonia.

Tissues or exudates from eleven clinical cases of rheumatic fever and from eleven cases at necropsy were studied. The following were cultured for pleuropneumonia-like organisms: synovial fluid four, pleural exudate three, pharyngeal washings four and heart valves with verrucous vegetations, pericardium or myocardium obtained at autopsy five. Similar material preserved by freezing from eleven of the cases was also cultured. In no instance were pleuropneumonia-like organisms recovered. The pleural fluid from one, and the synovial fluid from four

clinical cases, as well as tissue from three hearts obtained at autopsy, were inoculated onto the chorio-allantoic membrane and passed at intervals. No significant transmissible lesion was produced. Material from nine of the clinical cases and seven of the autopsies was instilled into the lungs of 145 mice and passages were made as previously described. In all, 486 mice were used. Sixty-seven mice were inoculated by other routes with material from two clinical cases and four autopsies. The results of these studies were similar to those described for rheumatoid arthritis.

Extensive cultural studies have been made in eighty-three cases of rheumatoid arthritis and twenty-two cases of rheumatic fever. No organism of significance has been consistently isolated.

DISCUSSION

DR. M. HENRY DAWSON, New York: Only one conclusion seems possible: if bacteria actually are present in the blood and joint tissues of patients suffering from rheumatoid arthritis they must exist in some form which cannot be detected by present day bacteriologic methods. Collier in Batavia, Java, has reported the occurrence of a spontaneous polyarthritis in rats. Cultures on the affected joints have been negative but the disease is readily transmitted from animal to animal. Findlay and his associates have described a similar disease in rats from which they have isolated a pleuropneumonia-like organism or "L form." I have had the opportunity of studying Collier's rats and have come to the conclusion that the disease is quite different from rheumatoid arthritis. Another interesting study has recently been reported by Collins on arthritis in swine. This disease is due to the organism *Erysipelothrix rhusiopathiae* and bears a closer relationship to the human disease. However, it is by no means clear that arthritis of swine bears any relationship to rheumatoid arthritis.

DR. HOMER F. SWIFT, New York: Dr. Brown and I made a preliminary report on the possible recovery of pleuropneumonia-like micro-organisms from rheumatic patients. We have now established that these micro-organisms probably originated from the mice inoculated with the exudates and have been unable to grow these germs directly from the exudates or tissues of patients with rheumatic fever. The technics have been so well developed that these negative results are significant. In animal inoculations Dr. Angevine and his co-workers used one strain of mice, of which about 10 per cent developed pneumonia. My associates and I employed another strain and obtained a much higher percentage of pneumonia, from which numerous pleuropneumonia-like micro-organisms were easily recovered when the pneumonic lung was rubbed over 30 per cent ascitic fluid agar and the plates were examined microscopically after from two to four days' incubation. In our studies mice inoculated with rheumatic exudates had a much higher proportion of pneumonia than did controls inoculated with nonrheumatic exudates. This suggests that possibly the rheumatic exudates contained aggrasin-like substances that made the pleuropneumonia-like micro-organisms carried by the mice in their upper respiratory tracts become more pathogenic; for, confirming Dr. Albert Sabin's studies, we have found that many of these mice carry in their conjunctivas these peculiar micro-organisms.

In reviewing the history of bacteriologic studies in rheumatism the question arises: Whence came the bacteria that have been reported as having been obtained? Outstanding among the various possible sources is the environment under which the cultures were made. Dr. Angevine's precautions in providing an atmosphere with little liability of contamination from air or other extraneous sources were important. In New York, at least, many positive cultures reported previously were made in Bellevue Hospital; and we know that in the old Bellevue Hospital it was difficult to find a good atmosphere, bacteriologically speaking. Before the advent of the automobile truck, horse manure was a prolific source of many streptococci in the air. Recently it has been shown that hemolytic streptococci are readily disseminated in the atmosphere of wards in which patients with scarlet fever or tonsillitis are treated.

Next arises the question of the significance of micro-organisms grown directly from blood cultures. When a tooth is pulled or tonsils are excised there is a certain period when bacteria, often

streptococci, actually circulate in the blood. In a patient with a sore throat it is conceivable that there is a period when streptococci break through the natural barriers into the blood stream. Obviously in the etiology of subacute bacterial endocarditis the agents infecting the heart valves must be bacteria carried originally by the blood. As already mentioned, when animals are employed to recover micro-organisms from a patient the difficulty always arises of determining whether the germs found are from the animal or patient. It should be indicated that the studies of Dr. Cecil and his collaborators have resulted in significant positive results. A few years ago when they were recovering streptococci from patients at Bellevue Hospital, he agreed to perform a blindfold test. The materials to be tested came from Presbyterian or Rockefeller Hospital and were sent to Dr. Cecil, who attempted to differentiate the rheumatic conditions in the patients from whom they came and made the correct diagnosis in many cases; but the differential feature was the agglutination by the serum of patients with rheumatoid arthritis of streptococci he had isolated from certain patients, and the absence of these agglutinins from the serum of patients with degenerative arthritis. Thus was discovered a test which many observers consider quite important. Lastly the discovery of the ability of pleuropneumonia-like micro-organisms to induce arthritis in mice and rats has led to a study of the beneficial action of gold salts in arthritis of these animals; and this type of experimental arthritis can be used to test the relative efficacy of various gold salts. I believe it has also been shown that other types of infectious arthritis in mice can be favorably influenced by these therapeutic agents. Thus, while the story is not finished, it still points to the value of experiments of this nature. Out of them progress is made toward an eventual solution of the mystery of arthritis.

DR. RUSSELL L. CECIL, New York: This is a negative report that seems to clear up a good many points. The studies of Drs. Nicholls and Stainsby were done at Bellevue Hospital; however, they were done in a sterilized room with great care and precaution. We were skeptical of these streptococci from the first. I think we were misled by the discovery of specific agglutinins in the patient's blood. Where did these streptococci come from? Dr. Nicholls and I often speculated about it when doubt was raised as to the accuracy of the work. The late Dr. Park thought the streptococci were actually in the blood but questioned their significance. We now think the pipets were the most likely source of contamination, rather than the air, since hemolytic streptococci are not common contaminants in air or on the skin. We think that, in spite of the cotton plugs in the sterile pipets, possibly some streptococci from the operator's mouth were blown through the pipets and introduced into the culture medium. This seems about as plausible an explanation as any. It would be difficult to set out deliberately and get 50 per cent contamination with streptococci in cultures. Bacilli of various kinds are common but it is unusual to get so many streptococci. The study of Dr. Angevine and Dr. Rothbard does not look pretentious but the number of animals used and the number of cultures made represent a great amount of work. As Dr. Swift said, this negative study means a really positive contribution to the subject. From my standpoint this report is in the nature of a retraction. I hope that a few years from now I shall not have to retract the retraction. I do not think that is likely.

DR. JOHN W. GRAY, Newark, N. J.: I am interested in the almost total lack of positive blood cultures in this report. One would normally expect a higher percentage from complicating acute upper respiratory infection alone, and if such cases were excluded from these studies the results might be of significance. Dr. Angevine and his collaborators made some cultures on my patients at the Hospital of St. Barnabas in Newark, and these patients had received sufficient treatment so that the disease became more or less quiescent. I have observed that positive cultures are seldom obtained during the summer months and that the largest number is found during the winter and spring months, when exacerbations of the disease following acute upper respiratory infections are most common. Whatever the cause of bacteremia may be, the presence of bacteria in the blood stream does not prove the microbic etiology of rheumatoid arthritis, nor does the absence of bacteria disprove it. I like Dr. Hench's conclusions regarding the infectious etiology of this disease when he

stated that as an investigator he must conclude that the evidence for infection, although impressive, is incomplete, but as a practicing physician he could not wait until evidence is complete and must commit himself, with reservations, to the microbic theory.

DR. R. H. FREYBERG, Ann Arbor, Mich.: About a year ago I became interested in the possible relationship between pleuropneumonia infection and the various rheumatic diseases, especially rheumatoid arthritis. With the assistance of Dr. Bauer and his associates, Dr. Dawson and others, I set about attempting to obtain cultures of pleuropneumonia-like organisms from synovial fluid, blood, subcutaneous nodules and the synovium itself of patients with rheumatoid arthritis primarily and of a few patients with rheumatic fever. All of the results have been entirely negative.

DR. J. ALBERT KEY, St. Louis: I had some negative results too in trying to obtain cultures of organisms from patients with rheumatoid arthritis, but changes which are practically identical with those found in rheumatoid arthritis can be produced in experimental animals by streptococci, although the polyarthritis which has been mentioned has not been produced. From the standpoint of the clinical course of the disease and from the standpoint of the pathologic changes that occurred in the tissues and also from the unexplained agglutination of streptococci which occurs in the blood of these patients I should regard this as an infectious disease. In spite of the sometimes positive, sometimes negative observations, statements and retractions, one may be prepared some day for Dr. Cecil to retract his retractions.

DR. CHARLES W. WAINWRIGHT, Baltimore: I should like to ask the authors concerning the status of the agglutination reaction in their cases of rheumatoid arthritis because this has been to my mind an important contribution in the study of this disease, provided they represent true agglutinins. There are many features about the reaction which point to true agglutinins and, on the other hand, features which indicate that it might be some curious physical-chemical phenomenon peculiar to this disease.

DR. T. DUCKETT JONES, Boston: During the past three or four years my associates and I isolated, according to the technic which Dr. Angevine described, a virus from the heart tissues of several patients with fatal rheumatic fever. The changes developing in the lungs of mice were interesting. The blood of the rheumatic fever patients neutralized this virus. The following year, however, we had less luck in isolating a virus from patients with fatal rheumatic fever. We tried not only cardiac but pulmonary tissues. To summarize, it soon became evident that the virus which was isolated was similar to the virus which can be isolated from patients with influenza. What this means we do not yet know. There are many other factors that come into play. The pleuropneumonia-like organisms and the question of mice viruses also enter the picture. We have isolated some which are similar to the noninfluenzal viruses recently described by Horsfall. Others isolated from stock mice behave much like the influenzal viruses. We now feel that we have isolated an influenza-like virus from rheumatic fever patients and from the respiratory tract rather than the heart. Whether it has any direct bearing on rheumatic fever it is impossible to say, but further studies of the presence of neutralizing antibodies in rheumatic fever patients may prove to be interesting.

DR. D. MURRAY ANGEVINE, New York: I should like to say something about the recovery of micro-organisms from the blood stream. One can take a blood culture on a pig at almost any time during twenty-four hours and recover organisms from the blood stream. Blood cultures can be taken from patients after a meal, and frequently organisms are recovered. If the blood of normal rabbits is repeatedly cultured, organisms may be recovered in perhaps 5 per cent of instances. In addition to the intrapulmonary route, we have injected mice intravenously, intracerebrally, intraperitoneally and into the foot pad. Dr. McEwen took cultures of the blood of various patients over a period of two years. It is of interest that in one year 20 per cent of the cultures were positive, whereas in the other year the incidence was much lower. I did not intend to mention the streptococcus agglutination reaction for we are still in a state of flux concerning it. When we began our work, a good many positive tests

were obtained. However, as we have continued, there has been considerable variation in the results. During a period of four years, out of about 300 agglutination tests on definite cases of rheumatoid arthritis, our percentage of positives would be about 45. This is approximately the same figure as that reported by Dr. Bauer. Dr. Key suggests that we are getting away from the infectious theory of this disease. I may say that we have been continuously working along this line in animals. Two years ago in a report before this society, we showed pictures of what we thought were rather typical of the pathologic changes usually seen in rheumatoid arthritis. They showed lymph follicles produced by streptococci. So far we have not been able to obtain these lymph follicles in the synovia of any other animal except the rabbit.

Metabolism of Cartilage (Bovine) With Particular Reference to the Effects of Aging

DRS. OTTO ROSENTHAL, MORRIS A. BOWIE, and GEORGE WAGONER, Philadelphia: Cellular and metabolic studies have been made on bovine articular cartilage of varying ages. The cartilage from the older animals showed degenerative changes characteristic of hypertrophic arthritis. Microscopic examination and measurements of paraffin embedded slices of cartilage showed (a) the number of cells per cubic millimeter of tissue (cell content) declined with advancing age, and (b) the mean values of nuclear volume remained constant throughout the age groups.

The metabolic activity of surviving cartilage slices was determined by the method of Warburg. This activity was expressed as a ratio of metabolic rate to cell content. Glycolytic activity and the activity of the dehydrogenatic and oxygen-activating components of respiration were determined for cartilage of various ages. (a) Glycolytic activity remained essentially the same in all age groups. (b) Dehydrogenatic activity was determined from the oxygen uptake in the presence of methylene blue. It likewise remained essentially unaltered. The dye-stimulated respiration was accelerated by the addition of dextrose, succinate, lactate and pyruvate. This acceleration indicated that the cartilage cell is endowed with enzymes for the dehydrogenation of these four metabolites. No detailed analysis was made of the main part of the dye-stimulated respiration which is based on utilization of tissue metabolites. The respiratory quotient (0.85) of these processes suggested oxidation of protein and fat. (c) The oxygen-activating component of respiration was estimated by measuring the spontaneous oxygen consumption of cartilage. The activity of this component declined 65 per cent from infancy to old age. This decline coincided and progressed with appearance and extension of the degenerative changes in cartilage.

Gradual failure of spontaneous respiration with aging hinders the use of the dehydrogenatic processes which are important in cellular anabolism. When to this is added the diminution of cell content, it must follow that the intrinsic integrity of aged articular cartilage is materially weakened.

DISCUSSION

DR. KARL MEYER, New York: Cartilage seems to be especially suited for a study like this because apparently its metabolism is fairly constant over the period of time in which one is working, and, second, because it is a relatively simple tissue in which one can study not only the energy production but also for what chemical processes the energy is used. To connect the energy metabolism with the production of chondroitin, sulfuric acid seems to be possible since there are methods available to determine the amount of hexosamine and from that figure calculate the amount of chondroitin sulfuric acid in cartilage. It would further be interesting to study the production of glycuronic acid in cartilage. Is the failure of oxidative processes which the authors demonstrated connected with a failure to oxidize dextrose or a dextrose equivalent into glycuronic acid? How does this total metabolism of cartilage change with age? It is said that apparently the total volume of the cartilage is not changed with age, though some of its components are. This may mean that the aging cells must produce some components other than the young ones. Apparently chondroitin sulfuric acid is replaced by connective tissue or other fibrous tissue for the pro-

duction of which not so much energy may be required. The production of this fibrous tissue may require quite a different type of metabolic activity from that of young cartilage.

DR. MARIAN W. ROPES: The onset of degenerative joint disease in the cartilage makes study of the alterations of metabolism with age of special significance. The value of this work has been greatly increased by correlating the analytic results with the number of cells. The low rates of metabolism are in accord with the avascular nature of articular cartilage and its limited reparative ability. However, while such work is essential, it is also extremely difficult to control and interpret. Great caution is necessary in drawing conclusions to avoid misleading results which would tend to bring essential studies of this type into disrepute. The conflicting results in this study and that of Bywaters make further work necessary. Apparently some of the determinations of Bywaters were on young cartilage, so that the differences cannot be explained entirely on age. The values of oxygen consumption are in such a low range that errors are magnified and all factors in the method become significant. I should like to ask how thick the slices were, whether one could be sure that oxygen was reaching all cells; whether control slices, heated to kill the cells, were used; whether the sterility was carefully checked, and how long the experimental runs lasted. Also I should like to know whether the slices were perpendicular to the surface as would be essential for comparable distribution of cells, and whether consecutive slices were used for metabolic experiments and microscopic study, both for number of cells and for degenerative changes, for especially in cartilage with degenerative changes there are great variations from one area to another. In any case it would seem almost impossible to rule out the errors from the clustering of cells that is known to occur. Was the change in specific gravity of the matrix considered in estimating the cell mass? If cartilage cells are larger in old age, as has been suggested though not proved, the calculation of cell mass would be incorrect and much if not all of the change in oxygen consumption with age could be explained. The magnitude of glycolysis in proportion to oxygen consumption and the predominance of dehydrogenase activity over the oxygen activating system have been well shown by Dr. Bowie's work. Whether the low respiratory activity decreases with age seems less conclusively proved. Its significance in terms of energy is changed only from 170 to 135 per cent from youth to age. Finally, whatever metabolic differences exist between young and old cartilage, there is no evidence that they are the cause rather than the effect of degenerative changes.

DR. DAVID H. KLING, Los Angeles: Dr. Bywaters has proved that articular cartilage is a tissue of low metabolism. The objection of the authors that he worked with old cartilage of reduced metabolism does not appear to invalidate his results because he conducted a comparative study of metabolism of synovial membrane and cartilage from the same joint. He found that the oxygen consumption per cell of cartilage was less than one-hundredth of that of synovial cells and, although glycolysis was higher, it amounted to only one-eighth that of synovial membrane from the same joint. Articular cartilage is an avascular tissue. Nutrition is of less importance for maintenance of integrity of avascular tissues than protection. It was experimentally proved that, if articular cartilage is exposed to drying or to pH values below 7, erosion and degeneration take place. Jones has demonstrated that friction due to movement of joints without lubrication results in heating and rapid deterioration of articular cartilage. This evidence indicates that the most important factor for the maintenance of proper lubrication and protection of the articular cartilage is the synovial fluid. Pathologic changes of this fluid, perhaps also disturbances of the blood supply of the synovial tissue with increased age, appear to be more significant than deficiencies of nutrition for development of degenerative changes of articular cartilage.

DR. OTTO ROSENTHAL, Philadelphia: The presence of glycolytic and dehydrogenatic enzymes in articular cartilage was shown by Bywaters when he found that cartilage split dextrose to lactic acid and consumed oxygen after the addition of methylene blue. The nature of the dehydrogenatic processes was not demonstrated by Bywaters. Dehydrogenases without oxygen-

activating enzymes are of little value for the function of a cell. A cartilage cell endowed solely with glycolytic power could hardly produce the variety of substances which constitute its matrix. Therefore it seemed to us of interest when we found that young cartilage has a definite respiratory power and when it was possible to elucidate to some extent the nature of the dehydrogenatic processes. Qualitatively the metabolism of cartilage does not differ as greatly from that of other tissues as was assumed. A detailed study of the oxidative enzymes was not attempted because it would have required the use of tissue extracts. We restricted our studies to the reactions of surviving tissue. The presence of catalase, therefore, was not investigated. Indophenol oxidase is apparently present in cartilage, since paraphenylene-diamine is oxidized by the slices. As Dr. Meyer pointed out, it would be of importance to find out what the cartilage cell does with the energy it obtains from either glycolysis or respiration. To solve this problem we must study anabolism and catabolism of cartilage constituents such as chondroitin sulfuric acid. It might be worth mentioning that cartilage splits one constituent of this acid, namely galactose, and that the enzyme involved is different from the glycolytic enzyme. The mechanism of this enzymatic process remains to be solved. Since the respiration of cartilage is constant over a period of from three to five hours, it is not difficult to obtain reliable readings. The thickness of the slices was around 0.5 mm. in all the ages studied, i. e. the slices were sufficiently thin to guarantee optimal oxygen supply. Oxygen consumption as well as glycolysis and dehydrogenation disappear completely after immersing the vessel with the slices for six minutes in boiling water. I think we can deny with certainty the question as to whether a miscalculation of the cell content could have accounted for the respiratory decline in the aging cells. Our assumption that the cellular mass is proportional to the cell content of the fixed tissue is tentative. An estimate of the shrinkage of the tissue in the course of the embedding procedure and a separate determination of the specific gravity of the cells and of the matrix in the age groups were not possible. But we believe that the magnitude of the cellular activity was obtained without applying these corrections. Even if we disregard completely these data, the respiratory failure with aging remains a fact because the ratio of respiration to glycolysis decreases with advancing age to the same extent as the ratio of respiration to cell content. With regard to the cause of arthritis, we never claimed that the respiratory failure in aging cartilage is the only cause of degenerative arthritis, but we believe that it is an intrinsic factor of aging. So far I think it has been of some advantage to replace one vague term by a definite process.

Latent Brucellosis: Its Importance in Association With Joint, Muscle and Nerve Pain

DRS. WARD DARLEY, and R. W. GORDON, Denver: If the intradermal tests with Brucella antigen is a reliable index to Brucella sensitization, the use of the test in a large series of patients should be of value in indicating the possible importance of Brucella sensitivity in certain chronic illnesses, particularly those in which neuroskeletal-muscular complaints are prominent. Of 1,027 "ailing" and 360 "well" individuals tested, 15.48 and 8.88 per cent respectively gave positive reactions. Of 159 positive reactors only fifty-four were found in whom a positive skin test was the sole objective finding and in whom there appeared to be no complicating neurosis. In this group neuroskeletal-muscular complaints stood second in incidence (62 per cent). Of 124 patients with hypertrophic arthritis, 13.7 per cent gave positive reactions. Eighteen per cent of eighty-nine patients with infectious arthritis gave positive reactions. Symptom comparison of the skin negative cases in this group with the fifty-four uncomplicated reactors, except for the constancy of joint complaints, revealed in general a lower incidence for all the symptoms tabulated.

Of 301 patients with personality determined disorders 26.5 per cent were positive reactors, and of 159 reactors eighty, or 45 per cent, had maladjustment problems. Fifty-eight Brucella sensitive patients were found in whom the only other observations were functional in nature. Symptom comparison of this group with the fifty-four uncomplicated reactors revealed little difference

except a much higher incidence of nervous and emotional complaints. One hundred nonreactor cases of personality maladjustment were also studied (as a control group) and it was found that the incidence of neuroskeletal-muscular complaints was essentially the same as in both the fifty-four uncomplicated reactors and in the group of fifty-eight cases.

In general we conclude, then, that *Brucella* sensitization is commonly found in patients with subjective neuroskeletal-muscular complaints whether they have associated personality problems or not. It would appear to us that each individual skin positive case should be carefully evaluated as to *Brucella* immunity or activity and as to the presence of personality determined disorders before mapping out therapeutic procedures.

DISCUSSION

DR. EPHRAIM GOLDFAIN, Oklahoma City: If *Brucella* causes psychoneurotic complications, then naturally the reverse is true. Psychoneurotic persons when seen by physicians should be investigated for latent brucellosis. Specific treatment of these psychoneurotic patients should be carried on concomitantly with other treatment measures, even if it is only an aggravating factor rather than a true cause of the individual patient's symptom complex. Briefly I wish to set forth observations noted as a result of routine testing by means of agglutination, opsonocytophagocytic, and cutaneous tests all cases seen in which arthritic or rheumatic symptoms were present. Where objective arthritic observations are present and other causes which explain the presence of the arthritis are lacking, except positive agglutination, opsonic index and cutaneous tests, there will quite often present itself to the examining physician the following outstanding subjective and objective observations: 1. Periarticular swellings, often resembling a typical case of atrophic arthritis. 2. Cold, clammy skin of hands. 3. Lack of response to removal of apparent foci of infection. 4. Often lack of response to other therapeutic measures. 5. Presence on x-ray examination of a lack of bony tissue involvement yet the presence of swellings typical of atrophic arthritis. 6. Absence of marked secondary anemia. 7. Absence of streptococcus antibodies. 8. Moderately active red cell sedimentation test. 9. Quite regularly a high titer of agglutination for the *Brucella* organism as well as a high opsonic index test and a strongly positive persistent *Brucella* cutaneous test. 10. Neurasthenia.

DR. WILLIAM J. KERR, San Francisco: In recent years I have seen some of the more chronic or protracted conditions that may occur in connection with brucellosis. In general one sees a number of complications or later involvements similar to those seen in typhoid. I have seen osteomyelitis of the spine and osteitis of the bone of the face and the floor of the antrum, and a number of others have been observed and described. Drs. Darley and Gordon have brought up a question which has been in my mind for a long time. How can one differentiate the group of symptoms that these patients complain of from those seen in the neurotic or psychoneurotic patient or in the psychotic patient? I think the authors have shown that most of the symptoms are exactly those seen in persons who have been ill for a long time with any chronic disease. It is this same group of symptoms which are difficult to differentiate from the symptoms of toxic goiter. Aside from the greater incidence of fever in this group there is some suggestion that they may have chronic or prolonged effects of brucellosis, and there was little else that seemed of great significance. However, those who were chosen for the group of psychoneuroses or insanity states show a preponderance of symptoms in favor of anxiety states. I have seen quite a number of patients who were known to have had brucellosis and who have been observed for a period of several years. It seemed to me that in them the most difficult symptoms to control were the symptoms which have been described. I believe that there is no proof as yet that they are due to the infection itself or to the lasting effects of some hidden focus of some other infection of this general type, but they appear to belong to the symptoms seen in any chronic invalid. If one undertakes to treat these symptoms by vaccines, the only effect will be by suggestion. This may be justifiable, but I think it is bad medical practice, particularly since it tends to mislead one as to values in treatment.

DR. D. MURRAY ANGEVINE, New York: We have taken a good many agglutination tests on serum as well as a good many cutaneous tests both for brucellosis and for abortus infection. In no patient from the Arthritis Clinic of the New York Hospital have we found any indication that brucellosis is a serious problem in relation to arthritis in New York City.

DR. W. PAUL HOLBROOK, Tucson, Ariz.: The authors have presented a series of control cases and have proved that the presence of a previous brucellosis as evidenced by a positive cutaneous test has no more to do with the etiology or joint manifestations than a positive tuberculin test. In my part of the Southwest the finding of rheumatoid arthritis with brucellosis is certainly uncommon. I have always doubted that brucellosis can produce a typical rheumatoid arthritis. It may be that it does occasionally.

DR. R. H. FREYBERG, Ann Arbor, Mich.: In Ann Arbor we studied twenty-five patients who had typical rheumatoid arthritis and twenty-five other patients who came to the hospital complaining of symptoms of a rheumatic nature but whose disease was not characteristic of any common type of arthritis. We studied these two groups of patients in the same way by doing blood cultures for *Brucella*, by doing cutaneous tests and opsonocytophagic indexes, taking careful histories and making physical examinations. None of the patients in the first group had any evidence that we could consider indicated or allowed a diagnosis of brucellosis. Three persons in the second group had what we considered to be definite evidence of brucellosis; and six others had "possible brucellosis." From this study we concluded that joint symptoms frequently exist with brucellosis: acute arthritis may occur, but chronic joint inflammation seldom if ever results from brucellosis.

DR. E. STERLING NICHOL, Miami, Fla.: I would offer a word of caution about assuming too definitely that the neuromuscular complaints in chronic brucellosis are due to psychoneurosis rather than to the infection. Individuals afflicted with chronic brucellosis do poorly in the climate of southern Florida. After seeing a number of so-called psychoneurotic patients experience gross exaggeration of their neuromuscular complaints after migration to the latitude of southern Florida, I am of the opinion that an occult *Brucella* infection may account for some of these complaints, a view which has been substantiated in some instances by clinical investigation.

DR. WARD DARLEY, Denver: The biggest questions that confront most of us (as far as *Brucella* sensitization is concerned) are decisions as to the cause of the patient's symptoms and the selection of cases for treatment. I feel that one still has to depend for the most part on clinical judgment, but it is only natural that one should turn to the laboratory for help. Given a positive cutaneous test, one should decide whether the patient is immune and thus from the practical standpoint whether he is still actively infected. I am afraid that unless the various tests are properly understood they will only add to the confusion already so evident in the study of brucellosis. The agglutination reaction is usually negative in the skin positive cases. There is no agreement among investigators as to how strong an agglutination one must have before infection is considered active. Some investigators consider titrations as low as 1:10 as significant. Most investigators require titrations of 1:80 or more before considering a given case as one of active infection. There were about twenty of our patients who had agglutinations of 1:50 or above. The opsonic phagocytic index theoretically should be of value. It is a complicated procedure and its interpretation is a matter of controversy, even if done correctly. The complement fixation reaction may offer a possible solution to this problem. To date, reports in the literature are few as far as its application to brucellosis is concerned. The sedimentation rate is of no help. I do not want to be misunderstood regarding the relationship between brucellosis and psychoneurosis. I do not think that latent brucellosis can be used as an explanation for psychoneurosis. It is possible that *Brucella* sensitization may render an individual more susceptible to personality maladjustment. We do not feel that it can be a primary cause. In our experience psychotherapy, in these instances, is more important than specific anti-*Brucella* therapy.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Influence of Cobalt on Iron Transportation and Storage: Chemical and Histologic Study. K. Kato and Vivian Iob, Chicago.—p. 751.

Vitamin K in Hemorrhagic Diseases of Children.—Kugelmass points out that the wide range of fluctuation (a deficiency of as much as 80 per cent with no hemorrhagic manifestations and an excess up to 300 per cent without thrombotic phenomena) indicates the instability of the clotting mechanism when disease affects its components. Several hundred blood clotting determinations have led to the conclusion that prothrombin is not a determining factor in purpura, hemophilia or scurvy of infancy and childhood except in rare hemorrhagic disturbances (hemorrhagic disorders of the newborn, neonatal icterus gravis, hepatic pseudothrombophilia and hereditary pseudothrombophilia). They may be related to intestinal disorders preventing biliary absorption of vitamin K or to hepatic or bone marrow dysfunction interfering with the synthesis and subsequent liberation of prothrombin into the blood. Therefore vitamin K may raise blood prothrombin if intestinal absorption and reticulo-endothelial synthesis are adequate. Each case of neonatal hemorrhagic disease differs in its cause and course but the bleeding is invariably due to prothrombin deficiency. Nine of ten such cases showed marked depression in the prothrombin content of the blood with a corresponding lowering in the clotting time. Since the determining factor was consistently a decreased blood prothrombin the condition was designated acute hypoprothrombinemia. The mild form of the disease is undoubtedly self limited, as two of the ten cases were discovered only during routine clotting time determinations. Severe cases respond poorly to all forms of therapy in spite of early diagnosis. These have been associated with prenatal transmission of the disease indicated by the lowered prothrombin content of the expectant mother's blood. Vitamin K appears of equal value with blood transfusion in mild cases, the one forming prothrombin and the other providing it. But mild cases offer no final criteria because coexisting hematogenic jaundice may diminish its absorption and utilization and thus interfere with its synthesis. That vitamin K raises the prothrombin levels is no index of its efficacy in the presence of hemorrhagic disease characterized by injury to the reticulo-endothelial system. Therapy should not be limited to a precursor of prothrombin when the active substance, blood, is available. The routine use of vitamin K to protect the newborn from possible hemorrhagic disease is not indicated as there is ample prothrombin for clotting shed blood. Further abnormally high prothrombin levels cannot prevent blood from oozing through a damaged vascular system unless the entire circulation is clotted. The contention that the prevention of neonatal hemorrhagic diseases will diminish intracranial hemorrhage is only partially true, as the former is a disease of the blood and the latter a result of trauma to the vascular system. A normal blood coagulability does not preclude vascular injury and vice versa. The two diseases are more often mutually

exclusive than coexistent. In icterus gravis neonatorum the bleeding tendency depends more on the extent of damage to the liver parenchyma than on the degree of jaundice. The low blood prothrombin is probably a secondary manifestation of progressive hepatic dysfunction which interferes with the synthesis of prothrombin. A case of obstructive jaundice with hemorrhagic manifestations cleared on the second day following 1 cc. of vitamin K in oil given in conjunction with bile acids three times a day. The blood picture was within normal limits after a week of severe jaundice. In hepatic pseudothrombophilia accompanying infectious invasions or chemical poisoning the bleeding is due to a decreased production of prothrombin or fibrinogen or both in the liver with a resultant diminution in their concentration in the blood characterized by a markedly prolonged clotting time. A case of infective jaundice with hemorrhagic manifestations responded favorably to vitamin K. Marked hemorrhagic episodes in this condition are primarily determined by the qualitative defect in platelets, and therefore vitamin K is not indicated unless there is a coincident decrease in prothrombin during mild interim attacks.

Primary Splenic Neoplasms.—Goldberg reports one hemangioma cavernosum removed surgically as spleen and three primary neoplasms of the spleen: a solitary hemangioma cavernosum, a solitary microcystic lymphangioma and a multiple macrocystic lymphangioma. The three primary cases were encountered among 575 necropsies, in which there also were ten secondary malignant neoplasms. These ten neoplasms were obtained from ninety-eight cases of carcinoma, giving a greater incidence (9.8 per cent) of splenic metastases than is recorded in the literature. The case of cavernous hemangioma of the spleen consisted of a solitary nodule in an otherwise normal spleen and was apparently an early neoplasm. The cases reported in the literature are mostly large cystic hemangiomas. The microcystic lymphangioma consisted of a solitary nodule 8 mm. in diameter, apparently an early growth in an otherwise normal spleen. The stroma was quite cellular in places, containing lymphocytes, endothelial cells and budding vessels, and therefore the lymphangioma belongs in the category of a neoplasm. The macrocystic lymphangioma was composed largely of lymph spaces separated from one another by a fibrous and cellular stroma, and a few blood vessels. These last two tumors appear to be real neoplasms rather than simple telangiectatic areas, since the lymph spaces are separated by a cellular stroma containing budding vessels. They conform to Ewing's description of cystic and cavernous lymphangioma. The bulky hemangioma cavernosum removed from the region of the spleen is considered spleen. The light area in the center of this tumor was composed mostly of mucoid connective tissue and possibly was a stage in the formation of fibroma said to develop from a cavernous hemangioma.

Dark Adaptation and Vitamin A Deficiency.—Hecht and Mandelbaum determined the dark adaptation of seventeen men from 21 to 30 years of age before, during and after their stay on a vitamin A deficient diet. The data show that cone and

a favorable medium which contains peptone-like substances and that only a relatively low concentration of the drug is obtained by systemic administration of sulfanilamide, it is obvious why such administration is not effective.

Sulfanilamide and Internal Fixation for Compound Fractures.—Campbell and Smith studied the prophylactic action of sulfanilamide on infection in fifty-four compound fractures including those with internal fixation. The results were sufficiently favorable to warrant further use of the drug. The cases of fractures are divided into three groups: fresh compound fractures, old compound fractures with a previous infection, and compound fractures with an active draining infection. In a portion of the first series, from 15 to 20 Gm. of sulfanilamide crystals was placed directly into the compound wound and the wound was closed without drainage. After twenty-four hours sulfanilamide was continued by mouth, from 15 to 20 grains (1 to 1.3 Gm.) every four hours. Of the ten cases of the thirty-five in the first group in which infection developed, cultures revealed *Staphylococcus aureus* in five, Welch's bacillus in three, *Streptococcus haemolyticus* in one and the organism was not recorded in one. These figures would suggest that sulfanilamide had a less favorable prophylactic action on staphylococcal and Welch's bacillus than on streptococcal infections. Sulfanilamide or azosulfamide was administered as a routine to the seven patients of the second group; the average dose was 8 Gm. of the former or 10 Gm. of the latter for from twenty-four to forty-eight hours prior to the operation and for from three to seven days after operation until there was no longer any danger of infection. No infections ensued in these seven cases. In the remaining twelve surgery was performed in the face of an active draining infection. The dosage of sulfanilamide, or azosulfamide, was similar to that administered in the presence of compound fractures with latent infections. Bacteriologic studies showed *Staphylococcus aureus* in three, *Staphylococcus haemolyticus* in two, *Streptococcus haemolyticus* in two, and the observations in five were not recorded. There have been no infections following internal fixation in ten; union has occurred in ten and it is too early for prognostication in two. In a number of the operative cases draining sinuses persisted for several weeks to months but the wounds ultimately closed and the bones united. In no case was it necessary to remove any of the plates, screws, nails or wires. The results in this group were the most striking of the entire series. Comparison with comparable controls shows better anatomic and functional results following internal fixation in conjunction with sulfanilamide than when internal fixation and sulfanilamide are not employed. The authors conclude that the present impression of sulfanilamide is favorable but that more extensive investigation must be carried out with sulfanilamide and other chemotherapeutic agents before accurate evaluation will be possible.

Treatment of Cerebral Palsies.—Phelps points out that, according to surveys in various parts of the country begun a few years ago, it may be assumed that there are at least 150,000 cases of cerebral palsy in the United States. A survey of children from 2 to 16 years of age in Maryland showed a yearly occurrence of seven cerebral palsy births per hundred thousand of population. In other parts of the country surveyed this ratio is fairly constant. The percentage of cases found in the Negro race is much lower than in the white race. A study to determine what percentage of patients had sufficiently high mental status to become worthwhile members of society showed that, if the physical difficulties could be alleviated, 68.8 per cent had good mental ability and that 72 per cent have a mild or moderate handicap. The problem of the cerebral palsies includes a large number of patients who would justify the time and expense of treatment. Severity of involvement is not always a contra-indication to treatment. Treatment depends on a careful diagnosis of the particular kind of cerebral palsy: spastic, athetoid or ataxic. A complete muscle examination should be made in all cases. No operation should be performed on a spastic muscle without examination, as the condition of the antagonists is often the deciding factor in determining the procedure. In conservative treatment the flaccid and weak muscles must be protected from the weakening effect of undue stretching, and the spastic

muscles from the strengthening effect of the stretch reflex. With selective massage, careful exercise, appropriate splinting and protection a great change in muscle balance may be attained. The amount of surgery apparently necessary at first will be greatly diminished. In athetosis a muscle examination will demonstrate those muscles which move involuntarily and those which do not. Athetosis seems better conceived as an involuntary attempt to move a joint in a certain way than as an involuntary stimulation of any individual muscle. Therefore surgical intervention on the muscles, nerves or tendons has little effect. Joint stabilizations are exceedingly difficult. The discomfort of the patient following the operation is marked and there is much difficulty with pressure sores. In general, operative procedures are unsuccessful. In severe cases Putnam's procedure is helpful; it quiets the athetosis but does not increase function. The further use of curare should be watched with interest. Carefully graded and prolonged relaxation beginning with the least athetoid parts of the body and extended to the more athetoid extremities combined with motion from the relaxed position eventually brings satisfactory results. The treatment of ataxia is that of training the voluntary motor centers to take over the function of the damaged balance mechanism. It can be compared to the learning of any other skill, such as playing the piano, which in time is carried out almost without thought. Thus, with sufficient practice the skill of balance and directional control can be learned until eventually it becomes habitual. The ideal place to train these patients is in a school or institution where their physical and educational needs are met until such time as bad habits can be broken and rehabilitation carried out. There is great danger of old habits returning at home, because they are so closely bound up with the home environment. After discharge from the institution, treatment should be continued individually at least three times a week to insure fixation of progress. It should be decreased gradually over a period of years as skills are taught which take the place of exercises. Obtainable results lie in three fields—use of the legs, use of the arms and speech. Speech disorders are likewise spastic, athetoid or ataxic, and the same principles of treatment apply. Satisfactory results, judged by the standards of other crippling conditions, are obtained when care and treatment are sufficiently intensive.

Impediment to Circulation.—Macklin points out that air may leak into the connective tissue sheaths of the pulmonary arteries and veins from the surrounding alveoli and produce bubbles which interfere with the pulmonary circulation. With continued influx the air may travel along these sheaths to the mediastinum and accumulate there as large blebs which indent the heart and great vessels. The circulatory embarrassment resulting from this aberrant air may be serious and attended by dyspnea and cyanosis, and in children it may cause death. Often it clears up in a fortnight or less. Pulmonic interstitial emphysema is important clinically because of the encroachment by air bubbles on the space of the vascular system. Experimentally the air is propelled along the sheaths by the force of an artificial blast of air, but chiefly it is moved on by respiration, coughing, straining and other acts. Pulmonic interstitial emphysema and pneumomediastinum have been caused by excessive pressure in administering intratracheal anesthesia, which complication may be fatal. Atelectasis is an important primary cause and must always be looked on as a threat of air invasion of the pulmonic vascular sheaths. A tendency to alveolar leakage would seem greater in some individuals than others and may be inherited. Too sudden inflation of a lung at operation may precipitate a leakage. Interstitial emphysemas and their associated pneumothoraces are never spontaneous. There always is an immediate exciting and predisposing cause. Roentgenograms, particularly oblique ones, are of diagnostic aid, and prompt appropriate therapy may save many lives, especially of children.

Hyperactive Carotid Sinus Reflex.—In a group of eighty-four individuals suffering from what appeared to be a hyper-sensitive carotid sinus reflex, Goodrich was able to duplicate the attacks by pressure on the carotid bulb. Sensitivity varied,

so that only in the degree of reaction rather than in kind were some persons abnormal. Sixty-five of the eighty-four persons were men. The entrance complaint ranged from a few transient dizzy sensations to repeated attacks of syncope. Dyspnea, substernal pain, numbness and weakness occurred. Blindness, aphasia or aphonia were reported. Four patients had only gastrointestinal effects, although many had associated gastrointestinal symptoms. Earlier in this study the patients were exhaustively examined and many laboratory and technical tests were performed before a working diagnosis was made and treatment started. This consisted of advising patients to lessen spontaneous stimulation of the carotid sinuses by avoiding tight collars, abrupt motions, looking upward, singing and other activities leading to increased intracarotid pressure or to external mechanical stimulation. Medication to decrease the vagus reactions and to augment the activity of the sympathetic portion of the autonomic nervous system was utilized. Atropine or synthetic related drugs were most commonly used for vagus inhibition. Ephedrine sulfate and in some instances amphetamine sulfate was given and appeared to be helpful. Thyroid was used in the majority of cases. It was continued until all other medication was discontinued. If no symptoms recurred, continued thyroid medication depended on evidences of thyroid need, judged independently of the carotid sinus activity. Demonstrating to the patient that the origin of the attacks was known and that they could be produced at will restored his confidence. Correction of undesirable habits and ways of living resulted in the cessation of symptoms in one instance without any medication. Fifty-three of the eighty-four patients were treated, and thirty-two were completely relieved, thirteen were satisfactorily relieved (the major handicap was avoided), five required continuous treatment and two were not relieved; both of these had severe cerebral damage, and surgical denervation was not advised. Surgical denervation on the right carotid sinus of one patient brought about complete relief for one year, when symptoms recurred and the patient refused further treatment. The author concludes that hypersensitivity of the carotid sinus reflex becomes more frequent with advancing age and in persons with arterial hypertension. The symptoms are frequently considered heart attacks and digitalis, which is often prescribed, further sensitizes the reflex and exaggerates the symptoms. Electrocardiographic records indicate that the vagal effect is involved in the more dramatic symptoms.

Prevention of Diabetes.—Haist and his associates believe that sufficient information is now available to show that the production of diabetes in experimental animals by pituitary diabetogenic substances may be prevented by dietary means or by large doses of insulin. Their studies of the factors which affect the insulin content of the pancreas support those of previous workers who approached the problem from other directions. The experimental prevention of the diabetic condition by certain procedures makes it imperative that their curative effect be investigated. In considering the relation of their results to the treatment of diabetes in human subjects, the authors assume that the factors which prevent the condition from developing will also tend to limit its progress. Fasting, fat-feeding and insulin prevent or hinder the diabetic state under experimental conditions. These procedures affect the pancreas in a manner opposite to that of high carbohydrate diets and prevent the deleterious effects of anterior pituitary diabetogenic principles. There is no evidence that factors which rest the pancreas cause permanent damage to islet cells, whereas factors leading to overactivity may produce permanent changes. If a clinician is

convinced that the patient will be benefited by stimulation of the islet cells, diets rich in carbohydrate are indicated. When such diets are used in animals the islet cells may be protected by providing large amounts of insulin. However, if the physician believes that the pancreas should be rested, fasting, fat-feeding and insulin may be employed. When extensive destruction of the islet cells exists he may decide that there is no point in resorting to these procedures. Under other conditions a reduction of the strain on the remaining islet cells may restore some exhausted cells and thus improve the diabetic condition. This would seem to be particularly true in the early stages of the disease. In animals the exhausted cells retain for some time their ability to recover. The interval during which the cells of man may be exhausted but still be capable of recovery is unknown. Resting procedures prevent the degenerative changes from occurring in cells not already affected and permit restoration of the exhausted cells retaining such ability. Wide departures from the normal diet are permissible for only short intervals. Over longer periods nutritional requirements must be satisfied, especially for growing children, for whom only minor alterations are justifiable, in which case insulin may be the method of choice. The prophylactic administration of insulin to potentially diabetic patients may become an accepted clinical procedure in the future. The authors suggest that the incidence of diabetes should be investigated among two large and comparable groups of children with a familial history of the disease. One group should be given a normal diet and the second a diet as low in carbohydrate and protein and as rich in fat as is physiologically feasible. The second group might be given limited amounts of insulin. The authors appreciate the inherent difficulties of such a clinical investigation but believe that the goal justifies the endeavor.

Preoperative Irradiation in Carcinoma of Breast.—Halley and Melnick observed radiation necrosis of tumor cells, associated with hyperemia, cellular infiltration, granulation tissue proliferation and fibrous and vascular changes after administration of massive doses in transplantable rat tumors.

After fractional and protracted irradiation the most radiosensitive cells are destroyed by necrosis, but the remaining resistant cells undergo mutation-like alterations. The small daily doses transform them into pleomorphic abnormal forms, giant tumor cells which result from the direct action of radiation on the tumor cells and not from secondary reactive mechanisms. These giant cells do not degenerate by necrosis but by calcium deposition in their nuclei. There is no fibrosis and no vascular damage. Normal tissues recover from the small doses. Much of the fibrosis and vascular obliteration obviously results from damage to normal structures by irradiation at an intensity too high or because of too large individual or total doses to allow normal tissues to recover. In the usual case of carcinoma of the breast amputated from two to three months after irradiation, much intact and uninjured cancer is seen. This has been interpreted by pathologists as tumor tissue which has escaped the action of radiation. The authors think that perhaps the actual irradiation changes which occur earlier were missed. Accordingly, earlier amputation was requested, and data were collected on 21 cases of breast cancer in which tumor doses ranging from 1,200 to 4,500 roentgens were administered over periods of from eleven to forty-nine days. The interval between irradiation and operation ranged from one to forty-five days. Operation was done when desquamation was complete and the skin became smooth and dry, making surgical cleanliness feasible. The microscopic changes in these cases correlate with those found in animal tumors. It seems logical, therefore, to conclude that irradiation by fractional method acts directly on human breast tumor cells by producing early radionecrosis of sensitive cells and later by accumulation of mutation-like effects through succeeding generations of daughter cells. The latter mechanism may easily be the more significant. Damage to the tumor bed does not occur under usual fractional irradiation. Regrowth of surviving tumor cells appears in from four to six weeks after therapy ends. If this is true, it would seem that a short preoperative course of irradiation fails to achieve optimal tumor damage, as the mutation-like effects require from four to five weeks of irradiation. Since tumor bed damage is slight under the fractional method, this mutational mechanism can well be followed to a full second degree cutaneous reaction. Surgery done within two or three weeks after irradiation has the advantage of a tissue in which viable tumor cells have been decreased to a numerical minimum. Further delay faces regrowth of the tumor. After from eight to twelve weeks operation is done with the tumor almost in its preirradiation state, with the probability of invasion and metastasis. There have been no complications in the 21 cases in which operation followed an acute cutaneous erythema. Healing seemed more prompt in the irradiated patients.

Megacolon Associated with Hydrocephalus and Optic Atrophy.—Worster-Drought and Shafar report a case of Hirschsprung's disease associated with hydrocephalus and optic atrophy. The somewhat obese blind boy aged 8 years was born prematurely of apparently normal parents and seemed to be of normal intelligence. He had suffered from obstipation since birth and for the last two years showed abdominal distention, with vomiting and diarrhea during the last year. Fecal discharges occurred every four days and were hard and bulky. A barium sulfate enema disclosed an enormous generalized dilatation of the colon. The encephalogram revealed symmetrical hydrocephalus. The optic fundi presented the picture of advanced bilateral optic atrophy with the vision of the right eye reduced to the mere perception of finger movements and with visual acuity of the left eye at 6/60. The authors, discussing the etiology and pathogenesis of the combined lesions, point out that in Hirschsprung's disease the hypertrophy cannot be accounted for by organic obstruction. The present tendency is to regard megacolon as a neuromuscular dysfunction due to an imbalance between the sympathetic and parasympathetic divisions of the autonomic nervous system. What constitutes the exact nature of the imbalance is still disputed. In hydrocephalus three mechanisms may be involved: (1) obstruction to the circulation of the cerebrospinal fluid, (2) defective absorption and (3) excessive secretion. Obstruction in the pathways of the cerebrospinal fluid is the commonest cause of congenital hydrocephalus and arises either from developmental abnormalities or from inflammatory processes or fibrosis, secondary to intracranial hemorrhage sustained intra partum. Defective absorption may arise from hypothetic infection involving the arachnoid villi or from maldevelopment of these structures. The cause of hypersecretion of cerebrospinal fluid by the choroid plexuses is still *sub judice*. Megacolon and hydrocephalus in the present case are assumed by the authors to have developed in utero. Hydrocephalus was, however, not progressive. Measurements of the circumference and diameter of the skull showed little variation from the normal. The underlying cause was either of a temporary nature or a defect that admitted of compensation. Congenital optic atrophy was regarded by the authors as secondary to hydrocephalus.

Fluid Administration for Surgical Shock.—King compared the value of several fluids for the treatment of experimental secondary shock in cats. Temporary recovery readily occurred in most cases of shock on the intravenous addition of physiologic solution of sodium chloride. The rise in blood pressure usually lasted from a few minutes to half an hour, after which it returned to the previous shock level or even lower. In severe shock intravenous physiologic solution of sodium chloride had little or no effect in raising the blood pressure. The rapid passage of the fluid through vascular endo-

thelium into the tissues explains the temporary effect. Therefore the practicality of its use is limited. When too much is given, pulmonary edema occurs. Often about 20 per cent of the normal blood volume can be given in the early stages of shock. Cardiovascular disease and degenerative changes in the vascular endothelium from prolonged anemia and anoxemia greatly increase the risk of pulmonary edema. In order to avoid cardiac failure, intravenous fluids as a rule should be given slowly by the drip method. The risk of pulmonary edema is greatest in the advanced stages of shock. The intravenous administration of hypertonic solutions of sodium chloride in shock causes an immediate rise of blood pressure and the rise is prolonged. The response is sudden and so marked that it bears little relation to the amount of fluid given. The prolonged effect is partly due to the altered osmotic pressure of the plasma in the circulation which causes reabsorption of tissue fluids. Blood pressure in shock can frequently be restored by water absorbed from the intestine. However, in many cases the alimentary canal does not tolerate fluids and vomiting occurs, in which case fluids may be given subcutaneously. Isotonic sodium chloride or dextrose solutions given by subcutaneous injection over a prolonged period restore blood volume and pressure in shock. The effect is prolonged and contrasts remarkably with the temporary benefit obtained from physiologic solution of sodium chloride given intravenously. In certain experiments subcutaneous fluid produced no effect on the blood pressure, and the animals died without showing any signs of recovery. These fatal cases were always severe cases of long standing in which the circulation was probably too stagnant for subcutaneous absorption to occur. Hypotonic solution of sodium chloride by the subcutaneous route was rapidly absorbed in most cases of shock and caused a gradual sustained increase of blood pressure when the circulation was stimulated by hypertonic sodium chloride solutions and when an osmotic gradient was maintained. It is seen from the experiments that the state of shock may be benefited by the addition of fluid to the circulation. The clinical application of the foregoing principles of fluid administration is proceeding. Several cases of severe shock have been treated successfully. In 1 instance the blood pressure recovered from the low level of 30 mm. of mercury.

Treatment of Chronic Mastitis.—Atkins states that a clinic for the investigation and treatment of chronic mastitis was attended by 212 patients with pain or with lumpiness in the breast. Previously he had defined chronic mastitis as "pain or lumpiness of the breast not due to bacterial inflammation, new growth or fat necrosis," a definition which frankly admits ignorance of the nature of the disorder. Early in the investigation it became clear that slight periodic pain in the breast and lumpiness sufficient to distinguish the breast from the surrounding subcutaneous tissue were commonly encountered among patients who never complained of their breasts. It was concluded therefore that the presence of these two symptoms did not necessarily imply abnormality. The definition of chronic mastitis thus tended to be confused until it was realized from microscopic studies that there was no definite distinction between the normal breast and the breast affected with chronic mastitis, the one merging imperceptibly into the other. A definition which makes such a distinction is undesirable and in fact impossible. In practice the author uses the term "chronic mastitis" to indicate pain or lumpiness in the breast of sufficient degree to bring the patient to the doctor. This implies that there are women experiencing these two symptoms who, because of fear of cancer or from some other psychologic cause, attend the mastitis clinic when their more phlegmatic

sisters with breasts similarly affected stay away. Thus a mastitis clinic becomes to some extent the resort of the apprehensive and the mentally unstable, and in assessing the effect of treatment it is important to take this psychologic element into account. The author did not feel justified in differentiating "mazoplasia" from "chronic cystiphorous epithelial hyperplasia," but the distinction between "epitheliosis" and "adenosis" has been of value in clarifying his idea of the histology of this disease, although he found that these two changes tend to occur together. Because of the psychologic element in painful nodular breast, it is necessary to exercise the most scrupulous control in investigating the effect of the various therapeutic agents. Six of the patients became pregnant while under observation and in 4 of them all symptoms disappeared between the fifth and sixth months. One of these 4 had had mastitis for many years and a previous pregnancy had caused the symptoms to disappear for eighteen months. The author examined the effect of estradiol benzoate given by injection or of the synthetic substance stilbestrol given by mouth. He found that the administration of estrogens in doses sufficiently large to affect the breast was found to be harmful, and it was thought that the microscopic changes were advanced by this substance. Androgens can alleviate the symptoms of most cases of chronic mastitis, but the beneficial effect is not permanent and undesirable concomitant effects, such as hirsuties, changes of voice, amenorrhea or disturbance of menstruation, may rob the treatment of its value. In 1 case of chronic mastitis, the only one of 212 to become malignant, carcinoma of the breast developed ten months after a course of testosterone propionate injections. The microscopic changes in the breast produced by androgens in doses up to the limit of tolerance are insignificant. Diathermy is of value in alleviating the pain in chronic mastitis, but its effect is liable to be only temporary.

Survival of Stored Red Cells After Transfusion.—According to Bushby and his associates, authorities have established organizations for supplying blood in large quantities in preparation for battle and air raid casualties. In the waiting period this stored blood was used for civil practice. Research was concentrated on the finding of diluents, anticoagulants, chemicals and other factors designed to ensure that the red cells would be sufficiently well preserved to survive in the recipient. Whether transfused red cells endure in the recipient cannot be determined by a simple blood count, because it does not show whether rises or falls in a total count are due to autogenous cells or to the transfused blood. The technic employed by the authors was to transfuse group O blood to a group A or group B patient. Counts of the recipient's blood were taken at intervals, a 1:101 dilution being made with the appropriate alpha or beta serum; the titer of the serums so used was 1:320. After being thoroughly mixed in the pipet, the contents were immediately expelled into a corked tube and incubated at 37 C. for an hour, being shaken at intervals of fifteen minutes. At the end of this time a drop was placed on a counting chamber and a count made of the "free" nonagglutinated cells which represent transfused group O cells. Before transfusion, the "nonagglutinable count," that is, the number of A or B cells not agglutinated by the particular alpha or beta serum, was determined for each patient. This number, which is assumed to be constant for each person, is subtracted as a correction from the "free" cell count before the number of surviving group O cells is calculated. The authors show in tables the percentage of cells surviving up to five consecutive days and at times up to twenty-five days, besides the quantitative fragility of the transfused sample and the amount of hemolysis present. When blood is collected into a 3 per cent solution of sodium citrate in the proportion of 100 cc. of citrate to 440 cc. of blood and stored at from 4 to 6 C., the following substances or procedures prolong the period of preservation of the red cells: adjustment of pH to 5 (of no value in practice), dilution and addition of dextrose. Of the single factors, dextrose is the best. The enhancement given by dextrose and dilution, or dextrose plus dilution plus acidification, is recognizable as such, but the degree is not sufficient to justify utilization for practical storage of blood. For the acute hemorrhage and shock of the wounded the prime necessity is to restore blood volume adequately. With restoration

of blood volume the efficiency of such oxygen-carrying elements is automatically increased. Brewer and his collaborators have reported that stored blood (containing dextrose) from ten to fourteen days old is as efficient as fresh blood for the treatment of acute hemorrhage. The survival figures determined by the authors confirm this statement and show that even older blood survives a reasonable time in the recipient and certainly long enough to keep a wounded man alive until he can receive complete surgical treatment. Such was the experience in recent campaigns, during which some 500 transfusions were given of blood from ten to thirty days old.

Obesity with Temporary Hypogenitalism.—Cerviño studied children between the ages of $7\frac{1}{2}$ and 14 years, nine of whom were boys, in whom obesity was associated with hypogenitalism. Some of the cases presented symptoms resembling Fröhlich's syndrome; others were differentiated from the Fröhlich type by a generalized distribution of adipose tissue and an exaggerated development of bones and muscles. Others again belonged to an intermediate type. Hypogenitalism in the cases simulating Fröhlich's syndrome was restored to normal conditions at puberty or later if retardation of puberty occurred. The various features of the clinical picture including personal and familial antecedents, age of onset, evolution, genital pathology, secondary sex characteristics and gynecomastia are discussed. Obesity with hypogenitalism dissimilar to Fröhlich's syndrome was found to date from birth or develop with the growing child and was found to continue after puberty and was observed either to undergo no modifications or to increase or decrease. In these patients the head was large, the cheekbones and chin pronounced and the diameter of the thorax and pelvis large for the age and the body build. The feet gave the impression of a flatfootedness that was only infrequently confirmed roentgenologically. Heredity played a significant part. There was also precocity in dentition and in the ability to walk and talk. The general health was good. The appetite was exaggerated but did not show the predilection for certain foods noted in the cases resembling the Fröhlich type. Laboratory tests indicated normal levels of glycemia or a tendency to hyperglycemia. The author regards obesity with hypogenitalism as due to modifications of the neurohypophyseal system. While the destruction of the anterior lobe by itself has not been demonstrated to induce adiposity, almost always damage to the hypothalamus is concomitantly observed. Damage to the anterior lobe could produce hypogenitalism with low physical stature but not obesity. In the intimate connection between these two organs lies the explanation of many of the symptoms observed in these cases. The transitory cases resembling Fröhlich's syndrome may be due to damage done to the hypothalamus if the regulatory processes of fat, carbohydrate and water metabolism are lodged here. At the same time the function of the hypophysis (anterior lobe) may be normal or excessive. In retarded puberty cases there may exist a temporary hypofunction of the hypophysis. Cases unlike the Fröhlich syndrome in which, besides obesity, is also seen a pronounced development of bone and muscles and occasionally a temporary hypogenitalism suggest hypercorticalism. However, a functional increase of chromophil cells of the anterior pituitary may be involved. Restriction of carbohydrate and fat consumption gives better results in cases dissimilar to the Fröhlich type than in those resembling it.

Anovulation in Women.—Clinical observations of 142 cases of sterility within a three year period enabled Novak to detect thirty-nine cases (age level between 22 and 43 years) in which sterility was due to anovulatory cycles. Anovulatory cycles were noted four times out of ten in patients between 20 and 25 years,

four times out of eleven between 25 and 30, three times out of seven between 30 and 35, four times out of six between 35 and 40 years and four times out of five between 40 and 45 years. Endometrial biopsy, performed in nineteen of the thirty-nine cases within a few days before menstruation, disclosed a non-secretory type of endometrium, with a proliferative activity that varied between clinical pictures corresponding to an early interval phase at one extreme and a marked Swiss cheese type of hyperplasia at the other. In eleven cases some degree of endometrial hyperplasia was encountered. In all cases menstruation was normal or approximately normal, though some showed a tendency to irregular tempo. In others the menstrual amount was above the average, though not pathologic. According to the author, failure of ovulation is to be considered a possible cause of sterility, especially in women approaching middle age. However, it is not usually advisable to perform endometrial biopsy repeatedly in women anxious to conceive lest it frustrate impregnation in a particular cycle. His observations tend to show that some women ovulate with some cycles and not with others, but that more frequently ovulation is likely to be completely in abeyance for considerable periods of time. Functional bleeding of the common type is merely an exaggeration of the anovulatory cycle. Since patients of this group exhibit no other evidences of endocrinopathy and are usually in good general health and since nonovulation may be a sporadic occurrence, therapeutic measures should be conservatively employed. Organotherapy with pregnancy urine preparations has not been successful. The effects of gonadotropic substances in pregnant mare serum on the human ovary have not yet been satisfactorily determined and require further investigation. The key to the riddle of why luteinizing fractions are released in some cycles and not in others seems to be locked up in the anterior pituitary.

Therapy of Eczema in Infants.—Bayer reviews various measures employed in the treatment of the eczema of nurslings, giving special attention to the dietetic measures. He thinks that some of the failures in the dietetic treatment are due to the fact that the same diet which has proved effective in some cases is used for all cases and that local measures are neglected. He is in agreement with Rietschel that it is not so much the nature of a diet as the change of the diet that effects improvement. Brushing is a valuable adjunct to the local and dietetic measures. In a disorder in which it is customary to avoid all external irritation, brushing seems at first contradictory, although it has been recommended for the treatment of eczema in adults. The author employed brushing for the first time in the treatment of a child with mild ichthyosis. Salicylic petrolatum and brushing greatly improved the skin of this child. Then the brush treatment was tried on the infiltrated skin of chronic eczema and of neurodermatitis. Unexpected results were obtained. In acute eczema the healthy portions of skin are brushed. The process is continued until the skin becomes red. After the acute stage has been overcome and redness and weeping have disappeared, the eczematous areas are likewise brushed with greater caution in the beginning than are the healthy skin areas. Brushing is particularly effective in cases in which the acute inflammatory stage is rapidly followed by infiltration or in cases in which the skin has become firmly infiltrated and unelastic. From eight to fourteen days of systematic brushings, together with other local treatment, often produces astonishing results in these cases. At the onset of the treatment the brush should be rather soft and, as the treatment progresses, harder brushes are gradually employed. The brushing is done while the child is given its bath and is continued for about ten minutes. During the first few weeks olive oil or liquid petrolatum is added to the water

of the bath. From 1 to 2 teaspoons of the oil is stirred into hot milk and the mixture is added to the bath water. The liquid petrolatum bath is helpful if the skin becomes rough. The brush treatment can be given in the ordinary water bath after the skin has become normal. The redness produced by brushing rapidly disappears and does not cause irritation leading to a flare-up of the inflammation. In addition to widening the capillaries and influencing the lymph stream of the skin, it can be assumed that the brushing also acts on the circulation. The increased blood perfusion of the skin doubtlessly increases the cutaneous metabolism.

Ectopia Cordis in Living Child Born at Term.—Kühnel reports an instance of abdominorachoschisis with total ectopia cordis in a living child born nearly at term. The malformation consisted in a broad slitlike median defect of the upper part of the abdominal wall and the lower part of the thoracic wall through which the heart was protruding. The heart was beating with a normal rhythm and rate outside the chest. The child was delivered spontaneously in cephalic presentation and showed no other malformations. It lived twenty-six hours and died with increasing cyanosis and dyspnea. The necropsy revealed that from the anterior surface of the heart a thin cord extended down to the amniotic membrane of the umbilical cord. Microscopic examination revealed that this cord consisted of amniotic tissue. The abdominal part of the slit was from 5 to 6 cm. in width, but it was not open, being covered by a thin membrane which was made up of an inner peritoneal leaf and an outer amniotic membrane. The thoracic part of the defect ended a little proximally to the middle of the sternum. The anlage of the sternum was defective, only the nucleus of the manubrium and the upper body nucleus being demonstrable. Only the three upper ribs were connected with the sternum. Opinions differ about the cause and development of the congenital ventral defects, but it is generally agreed that the development of these defects begins early in fetal life. The author emphasizes that a distinction has to be made between hernia proper, most often an umbilical hernia with its characteristic hernial sac, and the true cleft malformation, which either is entirely devoid of a sac or in which, as in the reported case, there is merely a thin covering consisting of peritoneum and possibly some amniotic elements. The term "congenital umbilical hernia" the author applies only to the true hernias, in which a greater section of the intestine, perhaps together with other abdominal organs (stomach, liver, and so on), is situated in the hernial sac. In the cleft defects the evenerations usually are far larger and more variegated. Morphologically and genetically these two conditions differ. Umbilical hernia involves the persistence and growth of the hernial anlage that is a physiologic phenomenon in early embryonic life. Up to the ninth to tenth fetal week there is always an intestinal loop present in the umbilical pouch on the abdominal wall. When the abdominal cavity becomes more spacious the entire length of the intestine is again withdrawn into the abdominal cavity. When this retraction of the intestine into the abdominal cavity is not complete, the result is "physiologic" umbilical hernia. Incomplete closing of the anterior body wall is a true malformation. Little is known about the etiology of these congenital defects, but it can be established that the incomplete fusion of the fetal abdominal wall originates early (about the fourth week) and that these defects are rare. It has been estimated that, whereas a large congenital umbilical hernia is seen about once in 5,000 fetuses, a cleft abdomen is seen only once in 17,000 and the combined abdominorachic defect is even more rare.

SHOULD SERUM BE USED IN ADDITION TO SULFAPYRIDINE

IN THE TREATMENT OF PNEUMOCOCCIC PNEUMONIA?

HARRY F. DOWLING, M.D.
THEODORE J. ABERNETHY, M.D.
AND
CLARENCE R. HARTMAN, M.D.
WASHINGTON, D. C.

The value of specific serum in the treatment of pneumococcic pneumonia has been recognized for many years. Recently the effectiveness of sulfapyridine in this disease has become equally well established. The indications for the employment of each of these therapeutic agents, the methods of administration, the results to be expected from their use and the possible toxic effects are by now almost universally known. What is not known, however, is the relative value of the two agents when either is used alone or when they are administered in combination.

In table 1 are shown the results of treatment with serum alone as compared with those following treatment with sulfapyridine alone in several clinics where comparative studies have been made. Pneumococci of all types were represented among the causative agents in these cases. Volini, Levitt and Campione¹ reported that 15, or 9.8 per cent, of 153 patients treated with specific serum died, as compared with two (3.3 per cent) deaths among 60 sulfapyridine-treated patients. Although complete data are not given, the disease seems to have been of equal severity in the two groups.

We² found a 16.7 per cent mortality rate, sixteen deaths among 96 patients treated with serum alone, as compared with a mortality rate of 11 per cent, fifteen deaths among 136 patients treated with sulfapyridine alone. The pneumonias were considered to be of approximately equal severity in the two groups, although there were possibly a few more mild pneumonias in the sulfapyridine-treated than in the serum-treated group.

Finland, Spring and Lowell³ treated 211 patients with specific serum, of whom 28, or 13.3 per cent, died. Among 225 patients treated with sulfapyridine alone, 40 died, giving a mortality rate of 17.8 per cent. The authors state that at first sulfapyridine was given only in the milder cases but that later its use was extended to all cases.

Rueggsegger, Hamburger and Cockrell⁴ reported a series of cases which had been treated alternately with serum and with sulfapyridine, respectively. Two (4.4 per cent) of 45 patients treated with serum died and 6 (12 per cent) among 49 patients receiving sulfapyridine. The age distribution of the patients and the percentage of patients with bacteremia was approximately the same for the two groups.

Bullowa and his co-workers⁵ rotated patients after type identification, treating some with serum alone, others with sulfapyridine alone, and others with the combination of the two. There were nineteen deaths among 111 patients treated with serum alone—a mortality rate of 17.3 per cent. Among the 124 patients treated with sulfapyridine alone, 10, or 8.1 per cent, died.

Among a total of 616 patients treated by all these investigators with serum alone 80, or 13 per cent, died; while among the 594 patients treated with sulfapyridine alone 73, or 12.3 per cent, died. As measured by mortality rates, therefore, the results of patients treated with sulfapyridine alone are approximately the same as those following treatment with specific serum alone.

Since sulfapyridine has been found to influence recovery from pneumonia by causing bacteriostasis of the pneumococci⁶ and since it apparently does not increase antibody formation in the host,⁷ one may assume that specific serum, by introducing passive antibodies into the host, would be a valuable adjunct to

drug therapy. In order to test this hypothesis, Spring, Lowell and Finland⁸ performed in vitro experiments by means of the pneumococcal test. They found that killing of pneumococci occurred more readily when specific serum and sulfapyridine were used in combination than when either one was used alone. Bullowa and his associates⁵ reached the same conclusion by the use of bone marrow cultures of pneumococci.

Several investigators have studied this problem in animals. Maclean, Rogers and Fleming⁹ found that 25 mg. of sulfapyridine was insufficient to protect mice

injected with 100 minimum lethal doses of type VIII pneumococci. When mice were vaccinated with killed pneumococci of the same type and seven days later given 100 minimum lethal doses they likewise died. However, if mice were vaccinated and seven days later received the infecting dose and also sulfapyridine, all of them survived. They were apparently fortified with antibodies from the vaccination and in addition had the advantage of the bacteriostasis caused by the drug.

Kepl and Gunn¹⁰ produced pneumonia in rats with type I pneumococci and treated some with sulfapyridine alone, some with serum alone and others with a combination of the two. Measured by mortality rates and by the length of survival among the animals that died, the best results were obtained in the group which received both serum and sulfapyridine. However, when Wright and Gunn¹¹ used the same methods to produce pneumonia with type III pneumococci there was no significant difference in the mortality rate following the use of serum and sulfapyridine combined, as compared with the mortality rate following the use of sulfapyridine alone.

Powell and Jamieson¹² infected groups of rats intraperitoneally with type I, II, V, VII, VIII and XIV pneumococci. In all types, with the possible exception of type VIII, the combination of sulfapyridine and specific serum resulted in a higher percentage of survivals than either agent used alone.

MacLeod¹³ found that sulfapyridine and serum were synergistic in infections caused by type III pneumococci in mice, since the number of survivors was greater when the combination was used for treatment than when either agent was used alone.

In view of the favorable results obtained by using serum in addition to sulfapyridine in vitro and in animal infections, the present study was undertaken to determine whether the same synergistic action would be obtained in a series of patients with pneumonia caused by pneumococci of types I through VIII.

MATERIALS AND METHODS

The patients were alternated between sulfapyridine therapy and specific serum plus sulfapyridine, as follows: As soon as a patient was admitted to the wards of Gallinger Municipal Hospital and the diagnosis of pneumonia suspected, the sputum was typed and a blood culture taken. No treatment, other than symptomatic, was given until a pneumococcus or other etiologic organism was obtained. If a pneumococcus belonging to one of the first eight types was identified, alternate treatment was given within each type, one patient being given sulfapyridine alone and the next sulfapyridine plus specific antipneumococcus serum.¹⁴ No exceptions to the strict alternation of cases were made on the basis of severity of the disease. Occasionally, when a patient was demonstrated by means of intradermal and intravenous tests to be hypersensitive to both horse and rabbit serum, that patient was given sulfapyridine alone and the next two patients in sequence were given the combination of sulfapyridine and serum, so that the series might be even again. This procedure was also employed for the few occasions when a patient had been started on one or the other therapeutic regimen and was subsequently found not to have pneumonia. A patient receiving any serum which was subsequently discontinued because of hypersensitiveness was nevertheless classified as having received combined therapy. If no type of pneumococcus was obtained from the sputum within six hours, treatment with sulfapyridine was begun and the case entirely omitted from the series.

There was no fixed dosage schedule for serum. The initial dosage was usually 100,000 units, but often a larger or smaller initial dose was given, depending on the severity of the illness and the duration at the time treatment was begun. If the patient did not show considerable improvement within twelve to twenty-four hours, or if pneumococci were cultured from the blood stream, additional serum was given. The average total dosage of serum per patient was 141,000 units. Thus it is evident that these patients received about the same doses of serum that they would have been given if serum had been administered without sulfapyridine.

The initial dose of sulfapyridine was 4 Gm. by mouth, followed by 1 Gm. every four hours until the temperature reached normal and remained so for three or four days. From that point on, the dose was gradually decreased and the drug finally discontinued after about six days of normal temperature. In the more severely ill patients the first treatment consisted of an intravenous injection of from 3.5 to 4 Gm. of sodium sulfapyridine.

Whenever the oral administration of sulfapyridine resulted in low blood levels, it was supplemented by the sodium salt intravenously unless the temperature had already fallen and remained down. The average total dose of sulfapyridine per patient was 40 Gm. among the patients receiving the drug alone and 36.9 Gm. among the patients receiving serum in addition.

RESULTS

In table 2 are shown the mortality rates by type. There were ten deaths among the 80 patients treated with sulfapyridine alone—a mortality rate of 12.5 per cent. Among the 82 patients treated with the combination of serum and sulfapyridine there were eight deaths, or 9.8 per cent. In each group of cases caused by an individual type of pneumococcus (with the exception of the cases caused by type III pneumococci) the mortality rate was the same or lower for patients treated with the combined method than for those treated with sulfapyridine alone. If the type III cases are excluded, there were six, or 9.2 per cent, deaths among the 65 patients treated with sulfapyridine and only three, or 4.5 per cent, among the 66 patients treated with sulfapyridine plus serum.

Thus it appears that when a comparison is made of the sulfapyridine-treated group as a whole with the combined therapy group as a whole, only a slight difference in mortality rate is evident in favor of the combined therapy group. However, when an analysis is made of the cases on the basis of several factors of importance in pneumonia, differences between the two groups become more apparent. These factors, which are shown in table 3, are age of the patient, area of lungs involved, the presence of bacteremia, the day of the disease on which treatment was begun and the presence of complicating diseases.

These data show, first of all, that the cases in the two groups were of about the same degree of severity. While a slightly higher percentage of patients treated

with the drug alone (as compared with those given the combination therapy) were over 40 years of age, had more than one lobe involved and had organisms in the blood stream, on the other hand a slightly higher proportion of patients receiving the combination treatment were treated after the fourth day of the disease and had other diseases complicating the pneumonia. These complicating conditions included acute alcoholism, congestive heart failure, diabetes mellitus, uremia, asthma, tuberculosis and pregnancy.

Among the patients under 40 years of age there were no deaths in the group of 49 who received sulfapyridine alone and only three (or 5.5 per cent) in the group of 54 patients who received serum plus sulfapyridine. There was a more striking difference among the patients over 40 years of age. Of the 31 patients in this group who received sulfapyridine alone 10, or 32.3 per cent, died, while among the 26 patients receiving serum plus sulfapyridine there were five, or 17.8 per cent, deaths. Thus the mortality rate of patients over 40 years of age was nearly twice as great for patients receiving sulfapyridine alone as for patients receiving sulfapyridine in combination with serum.

There were eight deaths (13.3 per cent) among the 60 patients in the sulfapyridine-treated series with one lobe involved and two, or 3.1 per cent, deaths among the 64 patients with one lobe involved who were given combined therapy. When more than one lobe was involved, the mortality rate was greater for those treated by the combined method (33⅓ per cent) compared with 10 per cent for those given the drug alone.

There was little difference in the two groups in relation to the presence or absence of bacteremia. There was an 11.3 per cent mortality rate among the sulfapyridine-treated patients with negative blood cultures and a 9.1 per cent mortality rate among those treated with serum plus sulfapyridine. In the group with bacteremia, 16.7 per cent of those receiving the drug alone died and 12.5 per cent of those receiving the drug plus serum.

Only 1 patient died (2.6 per cent of 38 cases) whose treatment with the combination of drug and serum was begun in the first four days of the disease, while 3 patients, or 6.4 per cent, died among the 47 given the

TABLE 4.—Rapidity of Crisis

		Number	Per Cent	Number	Per Cent
Sulfapyridine.....	70	12	17.1	28	40.0
Serum plus sulfapyridine....	74	28	37.8	44	59.5

drug alone at this stage of the disease. Among the cases in which treatment was begun after the fourth day of the disease, 21.2 per cent died when treated with sulfapyridine alone and 15.9 per cent died among those treated with sulfapyridine plus serum.

Among the patients whose pneumonia was uncomplicated by any other disease, 4 (or 6.1 per cent) died after receiving the drug alone, and only 1 (or 1.5 per cent) died among those receiving the drug plus serum. The mortality rates for the patients who suffered from other diseases along with pneumonia were practically the same for the two groups: 42.8 per cent for those receiving the drug and 43.7 per cent for those receiving combination therapy.

In table 4 is shown the relative speed with which the temperature reached a permanent level below 100 F. in the two groups. Within twelve hours after treatment was begun the temperature was below 100 in 12, or 17.1 per cent, of the 70 patients who recovered after treatment with sulfapyridine alone, as compared with 28, or 37.8 per cent, of the 74 patients who recovered after the combined treatment. After twenty-four hours the percentage of patients whose temperature was below 100 F. was still greater (59.5 per cent) in the group receiving sulfapyridine plus serum than it was (40.0 per cent) in the group that received sulfapyridine alone. These rapid crises occurred more frequently in the patients who received the combined treatment in spite of the fact that many of the sulfapyridine-treated patients received their initial dose of sulfapyridine by vein, whereas the initial intravenous dose was seldom given to the patients who received serum also.

COMMENT

On the basis of the results obtained *in vitro* and in animal experiments, one would expect to find, among patients treated with serum plus sulfapyridine a definite lowering of the mortality rate below that obtained when sulfapyridine was used alone. The two studies reported in which cases of pneumonia have been rotated for treatment by these two regimens do not seem to bear this out. Don and his associates¹⁵ reported on patients with type I and II pneumococcus pneumonia alternated in this manner. Among 49 patients who received sulfapyridine alone only 1 died, whereas there were three deaths among 37 patients treated with sulfapyridine plus specific serum. However, the dose of serum used was small, since patients under 40 years of age admitted within ninety-six hours of the onset received only 50,000 units and all other patients 100,000 units. No additional doses were given regardless of the course of the disease. This dosage would not be considered adequate for many patients receiving serum alone as treatment for pneumonia. Furthermore, the authors state that patients admitted during the night were started on sulfapyridine immediately and typing was postponed until the following morning. One wonders whether the treatment in the combined serum-sulfapyridine cases would not have been more effective if treatment with the two agents had been commenced at the same time.

Bullowa and his associates⁶ gave sulfapyridine to 124 patients, of whom 10, or 8.1 per cent, died, while 89 patients were treated with serum plus sulfapyridine with ten, or 11.2 per cent, deaths. When patients treated in the first four days of the disease were considered, there were five deaths among 53 patients given sulfapyridine alone and only one death among the 39 patients treated with sulfapyridine plus specific serum.

Our results show a slightly lower mortality rate when serum was used in addition to the drug than when sulfapyridine was used alone. When the type III cases are omitted, the results are still more favorable for the combined therapy group. The omission of type III cases may well be justified on the ground that there is no report, as far as we are aware, of any significant group of type III cases in which the mortality rate has

been definitely lowered by serum therapy. On the other hand, the prognosis in this type of pneumonia is particularly poor, the mortality rate being as high as, or higher than, that for pneumonia caused by any other type of pneumococcus. Even when sulfapyridine is administered, the death rate is still high. In our own experience there have been fourteen deaths, or 22.6 per cent, among a total of 62 type III pneumonias treated with sulfapyridine, alone or in combination with serum. These facts should stimulate further attempts to lower the mortality rate in this type of pneumonia by combined serum and sulfapyridine therapy.

Although bacteremia is one of the factors which profoundly affect the prognosis in pneumonia, the results obtained in the present series seem to show that sulfapyridine is equally effective when used alone or combined with serum. It has been repeatedly recommended that serum be given in addition to sulfapyridine when bacteremia is present. Our observations tend to question the necessity for this, unless other factors which make for a poor prognosis are present.

Serum seems to be particularly effective as an adjunct to sulfapyridine in patients over 40 years of age and in patients with only one lobe involved, especially when these patients are treated early in the disease. Since the death rate from pneumonia has been repeatedly found to increase progressively with the age of the patient, the superior advantage of combined therapy in the older age group is most welcome.

The relative cheapness and ease of administration of sulfapyridine will make it the method of choice in all cases except those in which it is definitely contraindicated. If our results are confirmed by other similar studies, they would suggest that every patient over 40 years of age seen within the first four days of the disease receive serum in addition to sulfapyridine. After the fourth day of the disease the value of serum as an adjunct is less. In order to give the patient the benefit of every possible aid, however, massive doses of serum might be given along with sulfapyridine to severely ill patients seen late in the disease. Sputum should be obtained for typing and blood taken for culture in every case before sulfapyridine is started, so that serum may be given, whenever it is indicated, as soon as the type is determined. This is necessary in order that the utmost advantage may be taken of the superior results achieved by the earliest possible administration of serum.

SUMMARY AND CONCLUSIONS

1. A series of cases of pneumonia caused by pneumococcus type I through type VIII have been alternated for treatment with sulfapyridine alone and with sulfapyridine plus specific antipneumococcus serum. The mortality rate was 12.5 per cent in the group receiving sulfapyridine alone and 9.8 per cent in the group receiving serum plus sulfapyridine. If the type III cases are omitted, the corresponding figures are 9.2 and 4.5 per cent, respectively.

2. Serum seemed to be particularly valuable as an adjunct to sulfapyridine in patients over 40 years of age.

3. Crisis occurred more frequently and was more prompt in the patients receiving serum in addition to sulfapyridine.

4. It is suggested that serum and sulfapyridine both be given to patients over 40 years of age with pneumonia and to those who are in need of a prompt defervescence.

EARLY OPERATION (SPINE FUSION) IN
UNSTABLE LUMBOSACRAL JOINTS

GILBERT E. HAGGART, M.D.

BOSTON

The problem of treating patients with the primary complaint of low back pain, often with sciatic radiation, continues to harass the orthopedic surgeon. This is true not only because of the difficulties in diagnosis so aptly expressed by Steindler¹ when he states that "It [backache] shares with the symptoms of headache the distinction of having almost unlimited possibilities of interpretation" but also because "So long as surgeons disagree in regard to the pathogenesis of chronic low back pain, there cannot be any uniformity of opinion concerning treatment" (Compere²). In spite of these limitations, the orthopedist is repeatedly called on to determine the etiology of this syndrome and then must he decide on whether to follow conservative or radical therapy.

Among younger patients with low back pain due to an unstable lumbosacral joint we at the clinic have been impressed with the results obtained from lumbosacral fusion and dismayed by the difficulty of achieving relief of symptoms through conservative methods on older poor risk patients who likewise exhibit an unstable lumbosacral articulation as well as marked degenerative changes in this area of the spine. It therefore occurred to me that some worth while information might be gained through a study of two groups of patients with low back pain due in my opinion to similar etiology—an unstable lumbosacral joint: group 1, older persons who had received conservative treatment over a period of years of which one year, if not the entire interval, was under personal supervision; group 2, younger patients treated by arthrodesing operations. Obviously, the two groups of patients are not directly comparable, but there is a definite similarity in respect to the history of onset and subsequent backache symptoms during the same age cycle, together with the degree of disability in this period which offers a reasonable basis for study. To clarify the situation, no patient is included with a clinical history or physical examination (including lumbar puncture, and, when indicated, spinogram study) that indicated herniation of an intervertebral disk.

GENERAL CONSIDERATIONS

Space does not permit a detailed discussion of the anatomic, physiologic and pathologic (as far as is known) factors of low back pain. These aspects have been extensively discussed in the literature. However, certain general considerations may be stated that indicate the basis for the approach to the problem.

I agree with Willis³ that "to understand properly the anatomical structures of the lower back and to appreciate its susceptibility to aches of obscure etiology, consideration must begin with the manner in which the lower extremities become attached to the vertebral column. In the evolution of man the pelvis has progressed toward the head by incorporation of the sacrum

and successive last number of vertebrae, the next preceding segment thereupon assuming the characteristics of the last lumbar segment." Of particular interest are the variations in the formation and articulation of the last lumbar and first sacral segments, where anomalies are common to all vertebrates and are, in the main, steps in an evolutionary shortening or lengthening of the presacral column. Variation in the number of presacral segments is of little importance in a discussion of backache, whereas the presence of asymmetrical sacralization and defective lumbosacral articulations is of definite interest in that they provide points of lessened resistance to stress and strain and, with a definite susceptibility, to muscle and ligament injury. Furthermore, the lumbosacral region is inherently weak "because as a structure developed for quadrupedal function with a support under either end of it [the spine] has been forced to manage a right angle turn and balance in the upright position, thereby acquiring mechanical imperfection and areas of exaggerated stress."

I therefore support the clinical concept advanced by Ferguson⁴ in 1925 and published in 1934 that lumbo-

Fig. 1.—The arrows indicate the most stable type of lumbosacral articular facets, namely when the articular surfaces face internal-external in relation to the midline of the body.

sacral anomalies produce symptoms only through faulty mechanics. As long as the muscles and ligaments are of sufficient strength and tone to enable the person to continue in his environment without fatigue there are no symptoms; that is, the patient is "compensated." Decomensation, and hence back pain, results from failure of the muscles and ligaments to support the lumbosacral area. This is particularly prone to occur in a spine which exhibits faulty mechanical structure because these muscles and ligaments "have less than normal capacity for meeting extraneous stress and strain since a certain portion of their total capacity is already in use." This conception is especially well borne out in the type of case here reported (group 1), which illustrates the fact that as one grows older the muscles lose their tone and power. In consequence, the person well compensated at 20 may at 40 not have sufficient muscle power to protect the lower part of the back from strains that were easily met in earlier years.

Since the principal cause of low back pain in these cases is fatigue strain in the soft tissues resulting from

From the Department of Bone and Joint Surgery, the Lahey Clinic. Read before the Section on Orthopedic Surgery at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

3. Willis, T. A.: Backache, an Anatomical Consideration, J. Bone & Joint Surg. 14:267 (April) 1932; Low Back Pain: The Anatomical Structure of the Lumbar Region Including Variations, *ibid.* 19:745 (July) 1937.

4. Ferguson, A. B.: The Clinical and Roentgenographic Interpretation of Lumbosacral Anomalies, *Radiology* 22:548 (May) 1934.

the structurally faulty mechanical construction or abnormally close relations of the bony parts, such a condition will often affect one side more than the other, or even one side alone. Furthermore, symptoms from the stress and strain need not be on the same side as the bony anomaly, for the most potent irritating factor is not

acquired and is due either to trauma, such as a heavy fall on the buttocks, or to degenerative changes in the disk, the result of faulty posture. Williams⁷ believes that this condition explains posterior displacement of the fifth lumbar on the first sacral vertebra, because settling of the disk segment takes place in a down and backward plane guided by the inclination of the sacral facets, and the more acute the lumbosacral angle the more marked is the posterior tilt of the first sacral facet and thus the greater the posterior displacement of the fifth lumbar vertebra.

POSTERIOR DISPLACEMENT OF THE FIFTH LUM- BAR VERTEBRA

It is my opinion that posterior displacement of the fifth lumbar vertebra on the sacrum is an entity and not an illusion. Repeated study of roentgenograms indicates that the decision

on this point lies in obtaining true lateral views of the lumbosacral area. When one is in doubt as to the presence of this anomaly, as these displacements are variable, a comparison of true lateral roentgenograms in extreme flexion and again in hyperextension of the lumbosacral spine and hip joint will decide the question.

Ferguson states that the mechanism of posterior displacement of the fifth lumbar vertebra on the sacrum occurs as follows: In the presence of a hypermobile lumbosacral joint due to the coronal type of articular facets, on hyperextension the fifth lumbar glides backward on the first sacral vertebra—an exaggeration of the normal motion—while on flexion, instead

necessarily the most obvious anomaly in the roentgenogram. Badgley⁵ and Hodges and Peck⁶ also emphasized this point in a study of 447 patients, of whom 27 per cent who complained of low back pain had anomalies of the lumbosacral region as opposed to 14.3 per cent with anomalies in a symptom-free control group.

DEFINITION

The term unstable lumbosacral joint is descriptive of a clinical entity which includes any arrangement of bony parts at the lumbosacral junction that is not adequate for support without undue stress or strain on the adjacent muscles and ligaments (Ferguson). Such an arrangement comprises one or more of the following mechanical faults: unstable lumbosacral facets (including rudimentary articular processes), bone defects in the posterior elements of the lumbosacral vertebrae, transitional vertebrae (sacralization and lumbarization), spondylolisthesis, abnormally acute lumbosacral angle and posterior displacement of the fifth lumbar vertebra on the sacrum.

A narrow lumbosacral disk may also be observed. Two types are recognized. One is congenital and is found in normal sacralization wherein the vertical diameter of the disk may vary between the diameter of the usual thick lumbosacral type and that of the thin sacral disk, as pointed out by Willis. It is doubtful whether this type is a cause of pain. The second type is

Fig. 3.—Bone defect in posterior elements of the lumbosacral vertebra. a, Usual anteroposterior view. b, View at 45 degree angle, same patient, illustrating the effective value of this film to show the defect.

of gliding forward, the fifth lumbar tilts forward as it is caught in the position of posterior displacement. Finally I believe that, as a minimum, 95 per cent of patients with chronic low back pain are best treated by a conservative regimen. This statement does not include pathologic conditions of the spine such as tuberculosis, primary neoplasms, fractures, osteitis or her-

niated disks. Thus among 2,000 patients with pain low in the back who were seen at the clinic from January 1936 to January 1939 fifty, or 2.5 per cent, were submitted to arthrodesing operations.

But it is also my opinion that in emotionally balanced younger patients of the age group from 30 to 45 years

85 per cent were between 31 and 35 years old. The fourth decade is the period when previously well functioning (that is, compensated) muscles and ligaments begin to weaken from lack of use. Then decompensation of these soft parts takes place and back symptoms result. It is also important to bear in mind not only

that these patients have experienced years of low back pain with attendant repeated efforts to ameliorate symptoms but also that in this interval all have accepted a definite reduction in the degree of their usual physical activities. This limitation is well expressed in the summary of the words of one patient: "I realized I had a weak back and therefore avoided activities that I thought might cause an acute attack or intensify my chronic low back pain."

The treatment of these patients in this clinic as well as elsewhere included all the methods of conservative

therapy with which we are familiar. Of effective methods there was one common denominator, namely bed rest. In many instances it is quite probable that persons would have experienced comparatively slight disability if they had carried out instructions consistently, especially in regard to muscle exercise and diet to reduce weight. But in our experience it is an exceptional patient who for years will follow such a regimen. Therefore, a younger person with low back pain due to an unstable lumbosacral joint not relieved by a trial

with persistent low back pain due to an unstable lumbosacral joint, and in whom a trial of adequate conservative therapy has not been successful, fusion of this articulation should be offered as a preferred method of treatment. Arthrodesis is indicated rather than to have the patient accept an often marked degree of permanent limitation of activities while he continues to experiment with various supports and different forms of physical therapy, as well as visiting a series of physicians in his effort to be rid of periodic bouts of severe low back pain.

ANALYSIS OF CASES

GROUP 1.—Herewith is a summary of the observations on seventy-five patients (fifty-four women, twenty-one men), average age 52, who had experienced disabling low back pain owing to an unstable lumbosacral joint over a period of from ten to fifteen years. In every case there was roentgenographic evidence of productive bone changes at the unstable articulation. Generalized degenerative arthritis of the lumbar spine was noted in eighteen cases of this group. This consistent finding of degenerative bone changes about unstable lumbosacral joints is significant not only as indicative of the mechanical unsoundness of the joint but also because this arthritis, when established, is an additional factor in the production of symptoms. Such arthritic pain would in turn have been avoided by a fusion operation earlier in life.

The onset of persistent low back symptoms in this group occurred in the age interval of 30 to 40 years;

of conservative therapy, should, I believe, be asked seriously to consider and, if possible, have a fusion operation performed, because a lumbosacral arthrodesis, when successfully carried out, eliminates the etiologic mechanical factor as well as preventing development of degenerative arthritic changes at the lumbosacral joint.

GROUP 2.—The following data summarize the results of arthrodesing operations on fifty patients (thirty-four

women, sixteen men), with an average age of 36 years, all with severe low back pain due to an unstable lumbosacral articulation. The average age at onset of symptoms was 32 years. Each of these patients had received an adequate trial of conservative therapy without permanent relief. Forty-six patients, or 92 per cent, were relieved of their back symptoms after spine fusion (from eighteen months to three years follow-up). There were four failures due to poor selection of cases. Two patients exhibited chronic arthritis originally thought to be localized at the lumbosacral joint but which proved to be a progressive process and spread to other levels of the spine. One patient was definitely a psychiatric subject, and this condition was not recognized in time to prevent the operation, and one patient who has a compensation problem has obtained no relief and, in my opinion, will not until definite arrangements are made for a pension. A postoperative roentgenogram on this patient shows a firm fusion.

CONCLUSIONS

1. The majority of patients with chronic low back pain can be relieved of their symptoms by conservative measures.

2. As a result of experience with one type of case—in which symptoms are due to an unstable lumbosacral joint—I believe that if a definitive trial of conservative treatment does not relieve symptoms, or if the mechanical arrangement of the bony part is very faulty, as for example in pronounced spondylolisthesis, then an arthrodesis of the lumbosacral spine is the best method of treatment.

Spine fusion is indicated because in these cases the pain and disability result from failure of the adjacent muscles and ligaments to support the back, owing to fatigue in consequence of the underlying faulty mechanical construction or abnormally close relation of the bony parts. Such decompensation of muscles and ligaments usually occurs between the ages of 30 and 45 and is most frequently observed from 34 to 39 years, when the person is no longer physically as active and hence muscle tone and ligament support are not so effective as in the younger age group.

3. While my experience with compensation cases has not been extensive, I agree with Compere that these patients are best considered for spine fusion after financial settlement has been made, unless there are marked abnormal changes at the lumbosacral junction.

4. Arthrodesis of the spine for low back pain is contraindicated in the emotionally unstable or psychiatric patient, as well as in the elderly person.

605 Commonwealth Avenue.

ABSTRACT OF DISCUSSION

DR. ALLEN F. VOSHELL, Baltimore: I am in accord with the principles given by Dr. Haggart under his conditions and only wish all would as carefully limit themselves as he has done. I wish he had reviewed his ideas on the "compensation back" and applied his fundamentals thereto. Not only is the diagnostic decision exceedingly difficult in this group but more so is treatment whether conservative or operative. The use of the same treatment for a noncompensatory as for a compensatory patient will most times result in an entirely different outcome. Almost all his cases are of the nonindustrial type, which might have some bearing on the speed of recovery and the high percentage of excellent results. I should like to ask whether his four cases of failure to recover and improve were due to non-fusion or to some other reasons. What type of fusion was followed? And over what area? Was the postoperative care

associated closely with muscle building and was physical therapy carefully controlled? If so, for how long?

DR. FREDERICK A. JOSTES, St. Louis: Most orthopedic surgeons who have had the opportunity to fuse lumbosacral joints because of backache have encountered the great difficulty presented by the compensation boards, insurance companies and the like. Some insurance companies have come to the point where they have flat-footedly said that no fusion shall be done in any patient of theirs. That, in my estimation, is a wrong attitude. However, before a radical procedure such as a spinal fusion is offered to a patient, one should offer him adequate conservative treatment, including firm support in the way of a bed and a brace, and his activity at least during that period should be limited. The burden of proof is on the man who sees the patient in his first attack of backache. I am certain that chronicity of back conditions may depend very much on the initial treatment. Such patients should have the usual supportive measures, gentle manipulation and complete rest for at least several days. It is most difficult to get these patients to rest, especially if one has been able promptly to relieve them of acute pain by manipulative procedure. Much time from usual activity and loss of working hours could be avoided in this way and recurrences are less apt to happen. It seems only fair that in selected cases in which extraneous factors such as compensation diseases or escape mechanisms have been definitely ruled out, given a young individual or even an older one who has repeated attacks of pain, repeated loss of time from whatever activity the patient indulges in or one who must so completely limit his activities as to interfere with his normal way of living, even though one can relieve him promptly of his pain in each attack, such persons should be offered the opportunity to be made free from attacks and pain and limitation of activity by a fusion operation. As suggested, compensation cases might be done after a settlement has been made. Promiscuous fusion, of course, is to be condemned.

DR. G. E. HAGGART, Boston: I did not go into the technical aspects of the fusion operation because of limited time. The fusion in these cases was performed on the lumbosacral joint except in patients with spondylolisthesis, where the fourth lumbar vertebra was included. The Hibbs technic, slightly modified, was employed. We do not transplant bone from the tibia as has been done in the past, but we do secure additional bone from the posterior superior iliac spine which can be exposed through the same incision, swung slightly to the side from which the bone is to be taken. The iliac spine is exposed by dissecting free the skin and subcutaneous tissue from over this area; the bone directly underneath is then denuded of soft parts, and it truly offers a "well" from which it is possible to obtain a large amount of soft medullary bone shavings which, when packed about the lumbosacral facets, are extremely helpful in producing rapid fusion. The length of time patients were kept in bed postoperatively was a minimum of six weeks; the average is seven. When the patient had to leave the hospital (via ambulance) for financial reasons or any other factors, he remained in bed at home a minimum of eight weeks. Just before he is allowed up the patient is fitted with a Taylor type back brace. While in bed he has not worn a support but lies on a firm fracture bed. This is much more comfortable than wearing a cast or brace in bed, which I do not think is necessary. When the patient is ambulatory, the Taylor back brace is worn three months on the average. In some instances it has been much shorter. This decision obviously depends on what the post-operative roentgenogram reveals, and we are guided by that together with the general condition of the patient. The point Dr. Voshell brings up about exercises is significant. Obviously, a back will not function simply because one has an internal bone splint. It is also essential to have muscle power. None of these patients were operated on until they had completed a preliminary interval of muscle training, which likewise they carried out after operation. The point I wish to emphasize about this group of individuals in their thirties with low back pain due to an unstable lumbosacral joint is that if they have developed in that age period severe disabling back pain and if a definitive, that is, a limited period of conservative therapy is not successful in relieving symptoms, then I believe the question of a fusion operation should be considered. In my opinion these patients should be advised to have an arthrodesis of the lumbosacral joint.

THE PATHOLOGY AND TREATMENT
OF OBSTRUCTIONS AT THE VESI-
CAL NECK IN WOMENHUGH H. YOUNG, M.D.
BALTIMORE

The pathology and treatment of obstructions at the vesical neck in women and the inflammatory conditions that lead up to them have received scant attention in the American literature. Two years ago I was able to collect and present thirty-six cases. I showed that the development of hesitation, difficulty in starting micturition, slowness of the stream, irritation, pain, hematuria and the presence of more or less complete retention of urine are quite similar to those conditions in men. On cystoscopic examination the mucosa of the urethra and adjacent portion of the trigon is inflamed, often edematous or even papillomatous. The trigon sometimes hypertrophies as a result of the obstruction. The bladder becomes trabeculated and sometimes cellular from back pressure and increased activity of the detrusors. Impairment of renal function may result from residual urine and back pressure effects on the ureteral orifices and the consequent dilatation of the ureters, pelves and thinning of the renal cortex. With

Fig. 1.—Autopsy specimen showing cross section of a prostate of almost normal male dimensions from a female with virilism due to adrenal hyperplasia.

the advent of infection the condition becomes aggravated and ultimately the results may be very serious.

I found that Caulk¹ was apparently the first to report the removal of the obstruction in one of these cases. He employed his cautery modification of my punch instrument. Since then other urologists have employed my simple cold cutting punch, the fulgurating punch of Thompson or the electrical resector of McCarthy. A few operators have attacked the obstruction suprapubically by excision or enucleation. Folsom and others have held that glands which they found in the region of the vesical neck of the female urethra are largely responsible for the persistence of inflammatory conditions and for the development of obstruction. In 1853 Virchow first noted stones in the female urethral glands resembling those found in the male prostate. He concluded that they were homologous structures.

From the James Buchanan Brady Urological Institute, Johns Hopkins Hospital.

Read before the Section on Urology at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

1. Caulk, J. R., and Patton, J. F.: The Cautery Punch Operation for the Removal of Obstructive Lesions at the Vesical Orifice in Women and Children. *J. Urol.* 33: 504-512 (May) 1935.

Since then many others have held that certain structures in the female urethra are homologues of the male prostate. Tourneux (1889), Magee (1892), Pallin (1901) and Eratt (1911) reported finding the presence of prostatic homologues in varying amounts along the entire female urethra. Eggerth (1915) pointed out that the anlage of the bulbo-urethral gland (Cowper's gland) and the major vestibular glands (Bartholin's glands) of the human embryo are homologous.

Fig. 2.—Appearance of two sections of a large prostate from a female with adrenal hyperplasia.

In 1922 Johnson,² working in this clinic, made the most exhaustive embryologic study of the vesical neck in the female. He made serial sections of female embryos of various lengths (60, 75, 150, 215 and 275 mm.) and from these prepared wax reconstructions that showed glands along the urethra from the vesical orifice to the meatus which, he asserted, corresponded to the prostatic glands in the male. Johnson asserted positively that "the whole homologue of the prostate in the female was here demonstrated for the first time." Johnson also studied by serial sections the glands of the

Fig. 3.—Section showing glands beneath urethra in vesical neck which correspond to prostatic glands in the male.

adult female urethra and concluded his study with the statement that the urethra in the female corresponded with that portion of the male urethra which lies between the prostatic orifice and the utricle.

Coincidentally with the formation of prostatic glands in the male, similar glands appear in the female. These prostatic glands in the female correspond in number

2. Johnson, F. P.: The Homologue of the Prostate in the Female. *J. Urol.* 8: 13-34 (July) 1922.

and give rise to branches, but they never attain the development of the male prostatic glands except when, as a result of hyperplasia of the adrenal cortex (the androgenic zone), these prostates in females continue their growth and ultimately almost attain the development of the male prostate. In the normal female these glands, according to Johnson, differ from the prostatic glands in being fewer in number, being less closely packed together, having fewer branches and showing much less evidence of active secretion. In "Genital Abnormalities: Hermaphroditism and Related Adrenal Diseases" I³ presented autopsies on three female pseudo-hermaphrodites in which great enlargement of the adrenals was found. In between the cortex and the medulla there was a tremendous development of the androgenic zone of Grollman characterized by the presence of many fuchsinophil cells. In these cases the prostate was considerably developed. The prostate from one of these patients is shown in figure 1. As seen here this patient, a woman of 26, had a prostate of almost normal male proportions. In figure 2 are shown sections of the prostate from another one of these patients. The similarity to the normal male prostate is evident.

At my request Dr. John Haines has secured sections from routine autopsies in the department of pathology. In figures 3 and 4 the typical appearance of these periurethral glands in the female is seen. The important role played by inflammation involving the urethra and the periurethral glands in the female is shown in the following case:

A woman aged 66 was admitted with complete retention of urine of eight months' duration. For a time there had been marked nausea, vomiting and severe uremia. She then began a catheter life and when she came to us her bladder was being emptied four times a day. Cystoscopy showed a contracted vesical neck with a posterior bar that was identical in appearance with that frequently seen in the male. The trigon was hypertrophied and the bladder was trabeculated and held 500 cc. of residual urine. With my cold cutting punch the obstruction was removed in three cuts. The patient left the hospital able to void normally and has now been followed for nine years.

Fig. 4.—Section showing suburethral glands near vesical neck, homologues of prostatic glands in the male.

The operative result is considered perfect. Photomicrographs of the tissue removed by the punch instrument in this case are reproduced in figures 5 and 6. As seen here, considerable inflammation of the periurethral glands in the formation of marked fibrosis is present.

3. Young, H. H.: *Genital Abnormalities: Hermaphroditism and Related Adrenal Diseases*, Baltimore, Williams & Wilkins Company, 1937.

This case is somewhat similar to others that we have studied. In most instances the obstruction has not been so complete or the gradual development so pronounced. In some much more fibrosis is present. In all it seemed evident that chronic inflammation played an important part in the case. We have in our files the

Fig. 5.—Section of tissue removed by punch operation on a woman with obstruction to urination (complete retention). Glands homologous to prostate surrounded by chronic inflammation and bar formation are seen.

case histories of some 500 women suffering with inflammatory conditions varying in degree at the vesical neck and the adjacent portion of the urethra. The

symptoms noted in the 101 cases studied in detail are given in the accompanying table.

On cystoscopic examination with the right angle telescope one sees only the conditions within the bladder at the vesical orifice. In the presence of a contracture or a bar, either posterior (fig. 7) or anterior, the condition is easily seen with this type of telescope. For lesions farther out in the urethra my antegrade telescope or the fore-oblique telescope of McCarthy is essential. With these instruments one sees all degrees of inflammatory change from simple urethritis to edema, irregular swellings of the mucous membrane, definite cysts and polypoid growths of varying degree (fig. 8). Rarely ulceration is present. The entire urethra generally shows a marked reddening and evidence of chronic inflammation. With the instrument in the urethra and a finger in the vagina, thickening of the urethra, par-

ticularly at the vesical neck, is often demonstrable. In some cases a definite stricture is present. Caruncles are not infrequently seen at the urethral meatus.

These cases present a common and often very troublesome condition in women that is often overlooked. The fact that the urine is usually normal, the cultures grow no bacteria and the ordinary cystoscope shows a vesical orifice that appears normal with the right angle telescope has led many observers to pronounce the urethra normal and to seek to relieve these patients by ureteral instrumentation. This is particularly true when pain in the back with attacks of colic in the region of one or both kidneys strongly suggests ureteral and renal abnormality. Benefit following cystoscopy and ureteral dilation not infrequently has been accepted as confirming the diagnosis, but such benefit may indeed be the result of urethral instrumentation rather than ureteral. As shown in 101 cases analyzed, the symptoms are apparently localized quite a distance from the urethra. It is therefore highly essential that, even when the history of the patient seems to point strongly to disease of the upper urinary tract, a very careful study of the urethra should be made, and if evidence of chronic inflammation and the various pathologic conditions described are present local treatment for the urethra and vesical neck is indicated, certainly as a preliminary measure before the patient is subjected to a series of ureteral dilations or operations on the kidney itself.

CONCLUSIONS

Chronic inflammatory conditions in the female urethra, especially in the deep portions and at the vesical neck, are common in women. They are accompanied by symptoms that are often referred to regions higher up in the urinary tract. In most cases, however, local symptoms are present in the urethra and bladder. Chronic inflammatory changes in the mucous membrane, in periurethral structures and particularly in the glands are often present and evinced by swelling, by edema, by cystic and polypoid formations and sometimes

Fig. 6.—Section showing fibrosis at vesical neck and submucous glands homologous to prostate.

by the development of definite bars or contractures of the vesical orifice. For the proper study of these cases an antegrade or fore-oblique telescope or urethroscope is essential. These lesions may often be missed during the course of cystoscopy with the right angle telescope. The conditions which produce such severe

local and referred symptoms are readily cured by endo-urethral treatment: applications of silver nitrate, fulguration, the punch operation or excision of the obstructing bar, or severely inflamed regions either with the simple punch instrument or the electrical resectoscope. Care must be taken not to overdo lest

incontinence for a time may occur. Accurate and adequate endoscopic methods often clear up these long standing and troublesome conditions.

ABSTRACT OF DISCUSSION

DR. HENRY DAWSON FURNESS, New York: I have been familiar with the work on the glands of the urethra; a German some years ago reported that he had found in some of these glands corpora amylacea. However, I don't believe I have seen exactly the kind of cases that Dr. Young reports. I have seen many cases of urethral obstruction with the retention and pathologic condition of the upper urinary tract; also patients with residual urine which I thought was more apt to be due to some cord lesion than to any obstructive lesion in the urethra itself. I see a few cases of urethral stricture, but even with those with rather marked obstruction I do not see much evidence of retention or urinary tract infection. Dr. Emmet, of the Mayo Clinic, recently brought out that in many of these cases retention of urine is due to a disproportion of the expulsive force of the bladder and the retentive force of the sphincter; that when the retentive force is disproportionately greater than the expulsive force there is retention and residual urine. I shall be on the lookout for the type Dr. Young has described. My experience has been mostly that in cases of retention there are cord lesions.

DR. ALF. F. GUNDERSON, La Crosse, Wis.: Dr. Young has called attention to an important condition which the average urologist rarely has occasion to see. The total number of reported cases of true intrinsic bladder neck obstruction in the female numbers only about 50 cases. The diagnosis is not difficult but one must exclude (1) gynecologic conditions such as uterine tumors and cystocele, (2) intra-urethral pathologic conditions—strictures, urethral diverticula, polyps, (3) intravesicular tumors and (4) hysteria. After exclusion of these factors one is aided by cystoscopy. Observers write about a bar, a ridge, fibrous contracture, hypertrophy of the internal sphincter that one can easily see through a cystoscope. I am impressed with the paucity of actual visible abnormality in the bladder neck in such cases. I would sound a note of warning! The female sphincter as seen through a urethroscope is often deceiving and gives one the impression of being the seat of a bar or contraction. One should attach greater importance to evidence of obstruction as found in the bladder—residual urine, trabeculation, saccules—rather than the appearance of the bladder neck. The amount of tissue present as an obstructing factor is truly disappointing. There is no uniformity of opinion with regard to the causation. Infection with resultant fibrosis and contracture with occasional hyperplastic glandular structures has been the generally accepted course of pathologic events. This theory was advocated by Caulk, Folsom, Van Houton and

others. However, Braasch and Thompson have been unable to demonstrate a greater amount of fibrosis in the removed tissue than there is present in the normal female bladder neck at necropsy. A greater amount of inflammatory cells has been seen as well as some hypertrophy of the epithelium and muscle bands. These observers feel that the inflammation, although the exciting cause, does not adequately explain the true basic etiology. They suggest an associated neurogenic cause: a nervous unbalance between the sphincteric musculature and the detrusor muscle which leads to a spasm of the sphincter, and subsequently to hypertrophy, and, finally, occasionally to active hyperplasia of the muscle. More evidence has accumulated to support this hypothesis by recent information obtained in the treatment of the neurogenic bladder or tabetic bladder by resection of the internal sphincter. Emmet in a recent publication has brought this forcibly to our attention. Resection of the sphincter as advocated by Caulk, Thompson, Emmet and others is merely an effort to facilitate emptying of the bladder by weakening one muscle against another or creating a more favorable muscle balance or readjustment.

DR. EDWARD N. COOK, Rochester, Minn.: The paucity of evidence that we see on cysto-urethroscopic examination around the bladder neck is the most interesting part to me of this problem. We must depend on our history concerning obstructive difficulty, small stream, frequent passage of the urine and occasionally the association of burning, the presence of residual urine and the appearance on cystoscopic examination, not at the bladder neck but rather in the bladder itself, such as trabeculation and cellulæ formation. This condition is worthy of our very careful consideration. It is true that not many cases have been reported. Thompson reported 24 at the Quebec meeting. We have had 12 cases since that time. Of interest is the fact that in most cases only a small amount of tissue will need to be removed. Occasionally one or two bites or nothing more than a sphincterotomy at times will relieve these patients of their symptoms. They are a group which have been treated unsatisfactorily for a long while, and I think we should pay more attention to them. As regards the pathologic conditions found I have not been particularly impressed with the amount of fibrosis and have not felt that this could be attributed to an inflammatory process; first, because of the fact that the inflammatory process in the female urethra is notoriously a frequent occurrence and yet obstruction in the female urethra is notoriously rare. Second, if one will examine the tissue removed in these cases and also examine postmortem tissue from the urethra in females that never had any difficulty with urination one will see little or no difference. It is possible that hypertrophy of the sphincter muscle as a result of spasm is the most common cause of the condition. In some cases a neurogenic dysfunction has led to sphincteric hypertrophy in my opinion.

DR. T. LEON HOWARD, Denver: If Dr. Folsom were here he would greatly appreciate the fact that Dr. Young has substantiated his observations, for he has insisted for many years that these are true glands and that they are often infected. Dr. Young's sections have proved that this is a fact. It seems to me that I see these patients every day. Others see them too, but if one is attempting to view the urethra and bladder sphincter with an ordinary Brown-Buerger cystoscope one is passing over the pathologic condition. If there is a disease condition present and one uses a fore-oblique lens cystoscope, there will be no difficulty in locating it and opening or destroying the polypoid-like growths with a fulgurating wire. This condition often begins during childhood, and patients go through life suffering from its effects. Pyelitis in children is frequently the result of infected glands in the posterior urethra, and until one cures these glands one cannot cure the pyelitis. Many pediatricians have failed to recognize this. It is astounding how many females have residual urine caused by these obstructing polypoid growths. If you suspect that they have residual urine and want to prove it easily, put ordinary liquid petrolatum in the bladder. If there is residual urine you will find liquid petrolatum floating on top of the next catheterized specimen whether it is obtained at the end of a week or a year. There is no guesswork about this test in either the male or the female patient.

DR. HUGH H. YOUNG, Baltimore: I have purposely not discussed cases in which there were spinal cord and other neurologic lesions present. These cases belong to a separate group. With proper urologic methods, including cystometric studies, they can be differentiated from the inflammatory and obstructive conditions to which I have limited my paper. Dr. Howard has emphasized the fact that with the ordinary cystoscope many of these conditions at the vesical neck in women are missed. My antegrade telescope or McCarthy's fore-oblique will show very well these changes at the vesical neck and in the deep urethra in women. They are indeed quite common and are responsible for many referred pains as well as many errors in diagnosis. I saw a woman recently who came because she had seizures of severe pain in the vesical neck. The ureters had been dilated many times; she had received orthopedic treatment, bladder lavage and stretching without relief. I found pronounced inflammatory conditions at the vesical neck with a little obstructive bar and much glandular inflammation. A small punch operation and treatment of the posterior urethritis with silver nitrate cured her completely. Another woman with very severe bladder and back pains had a large polyp and other inflammatory conditions deep in the posterior urethra and vesical neck. She had become a morphine habitué as a result of years of suffering. Local treatment relieved her. My simple tubular endoscope with application of silver nitrate, either by means of the stick or by means of 20 per cent solution on swabs, is usually entirely effective. Too much deep resection or fulguration is not advisable. When there is definite obstruction, the resection which I have described is very effective.

DIASTASIS OF THE DISTAL TIBIOFIBULAR JOINT AND ASSOCIATED LESIONS

RUFUS H. ALLDREDGE, M.D.

NEW ORLEANS

Diastasis of the distal tibiofibular joint is associated with extensive ligamentous rupture and results from external rotation or abduction injuries at the ankle. It may occur without associated fracture but is more frequently seen in cases of Pott's fracture in which there is fracture of the internal malleolus or rupture of the internal lateral ligament together with fracture of the lower third of the fibula. There may also be a fracture of the posterior aspect of the tibia extending into the joint.

Most articles in the literature on fractures of the ankle with rare exceptions¹ direct attention to the fractures of the malleoli and posterior tibial margin, leaving the impression that diastasis is of secondary importance. Undoubtedly failure to recognize and treat properly the diastasis may result in permanent disability even when the associated fractures are accurately reduced.

An effort has been made in this presentation to call attention to some practical points of importance regarding rupture of the distal tibiofibular ligaments and the associated injuries.

ANATOMY AND PHYSIOLOGY OF THE TIBIOFIBULAR JOINT

It is necessary here to review briefly the anatomic structures of the ankle joint which have direct bearing on the subject under consideration.

From the Department of Surgery, Division of Orthopedic Surgery, Tulane University of Louisiana School of Medicine and Charity Hospital and Touro Infirmary.

Read before the joint meeting of the Section on Surgery, General and Abdominal, and the Section on Orthopedic Surgery at the Ninety-First Annual Session of the American Medical Association, New York, June 14, 1940.

1. Merle d'Aubigné, R., and Smets, W.: Les formes frustes de déplacement externe de l'astragale dans les fractures malléolaires, *Presse méd.* 42: 157, 1934. Apfelbach and Boim.²

There is a definite but atypical articulation between the distal tibia and fibula, and the synovial membrane usually extends up between these two bones for a distance of about one-fourth inch.

Fig. 1.—End result of unrecognized and untreated tibiofibular diastasis compared to the normal ankle. Note osteo-arthritis and narrowing of joint space. Ankle fusion was necessitated by complete disability.

The distal ends of the tibia and fibula are bound together by rather weak ligaments. These ligaments are (1) the anterior lateral malleolar (anterior inferior tibiofibular ligament), (2) the posterior lateral malleolar ligament (posterior inferior tibiofibular ligament), (3) the transverse ligament, which is an extension of the posterior lateral malleolar ligament, and (4) the interosseous ligament, which is a direct extension of the interosseous membrane extending downward to the

Fig. 2.—Normal amount of separation of fibula from tibia when foot is dorsiflexed. Left, plantar flexion. Right, dorsiflexion. Note difference in width of tibiofibular joint space.

synovial cavity. The latter is longer in front than behind and occupies the space between the anterior and posterior malleolar ligaments.

Because the astragalus is 25 per cent wider in front than behind, it is necessary for fibular motion of some

type to take place at the ankle mortise when the foot is dorsiflexed, even though the mortise is also slightly wider in front than behind. Just what these motions are has not been clearly described. It has been said² that the fibula glides upward on its long axis when the foot is dorsiflexed and downward when it is plantarflexed. Efforts in this study to confirm this view have been unsuccessful. Measurements of x-ray films taken on the normal proximal and distal ends of the fibula do not show any movement in its long axis on extreme motions of the foot. It must be concluded, therefore, that the fibula does not glide upward or downward in its long axis.

It has been shown by taking anteroposterior x-ray films on the normal ankle that definite widening of at least 2 to 3 mm. takes place at the tibiofibular joint when the foot is dorsiflexed. Slight anteroposterior motion of the fibula has also been demonstrated at the lower tibiofibular joint by inspection of the fresh specimen. When the tibiofibular ligaments are sectioned, the fibula separates abnormally from the tibia when on dorsiflexion the foot reaches 90 degrees. The clinical importance of this fact will be indicated later.

DIAGNOSIS OF TIBIO-FIBULAR DIASTASIS

Clinical signs and symptoms of rupture of the ligaments and diastasis of the tibiofibular joint depend on the extent of injury and whether associated fracture is present. Frequently, when associated with a Pott's fracture, the signs and symptoms of the fracture completely overshadow those of tibiofibular ligament rupture and diastasis. Swelling and tenderness over the distal tibiofibular joint may be indicative when the fracture of the fibula is fairly high. This sign is of no value when the external malleolus is fractured. Gross ballottment of the fibula may rarely be present. Widening of the malleoli and abnormal anterior and posterior motions of the fibula may be seen when the ligaments are extensively torn.

Proper x-ray examination is important in every case. The preliminary use of local anesthesia may facilitate the taking of proper views. The x-ray examination should be considered as an adjunct in diagnosis and the surgeon should, if possible, be present when the x-ray films are made so that proper views will be assured. All anteroposterior views of the ankle joint should be taken with the malleoli equidistant from the x-ray film. The following views should be taken in all doubtful cases: (1) anteroposterior with the foot plantarflexed; (2) anteroposterior with the foot dorsiflexed; (3) anteroposterior view with the foot in external rotation; (4) lateral view with the foot in neutral position. If the usual anteroposterior and lateral views show dis-

Fig. 3.—Gross tibiofibular diastasis. Note abnormal width of joint space between internal malleolus and astragalus, loss of parallelism of joint lines of lower tibia and astragalus, and lateral displacement of astragalus.

2. Apfelbach, George, and Boim, Leon: Fractures of the Ankle. Arch. Surg. 35: 328-357 (Aug.) 1937.

tinctly the exact nature of the lesion and especially if gross diastasis is present in these views, the others may be omitted. Fluoroscopic examination is probably not as accurate as the examination of carefully taken x-ray films in the various positions.

A thorough understanding of the mechanism of fractures about the ankle is a prerequisite to proper interpretation of the x-ray films. It should be kept in mind that extensive ligamentous injury is as important as bony injury and may be diagnosed from the x-ray films alone.

The presence of an isolated fragment of bone between the distal tibia and fibula is a positive sign of diastasis and results from ligamentous avulsion of the outer border of the tibia. Rupture of the tibiofibular ligaments with diastasis is present in most cases in which there is a fracture 2 or 3 inches above the lower tip of the fibula associated with fracture of the internal malleolus or rupture of the internal lateral ligament.

Widening of the space between the internal malleolus and the internal aspect of the astragalus when the

Fig. 4.—A, note in addition to all signs indicating tibiofibular diastasis the fragment of bone avulsed from the lateral aspect of the tibia. B, same case after attempted closed reduction. Loose fragment of bone became interposed between the fibula and the tibia. C, same case after operative removal of loose fragment and fixation of fibula to tibia by means of a vitallium screw. Note accuracy of reduction of internal malleolus. It reduced spontaneously when the fibula was approximated to the tibia.

internal malleolus is not fractured indicates both a rupture of the internal lateral ligament and tibiofibular diastasis when the fibula fracture is fairly high.

Normally the external border of the astragalus is in line with the external line of the tibia and any deviation of this normal alinement to the lateral side indicates lateral displacement of the astragalus. Diastasis is a frequent cause of lateral displacement of the astragalus.

In the normal ankle the joint lines between the lower tibia and the superior border of the astragalus are parallel. Diastasis with lateral displacement of the astragalus is a frequent cause of loss of parallelism of these lines. Fracture of the internal and external malleolus or rupture of the internal lateral ligament are other causes of loss of parallelism of the joint lines.

Gross diastasis of the mortise with marked widening between the tibia and the fibula are usually recognized without difficulty. Complete diastasis with interposition of the talus is rare and occurs only when the ligaments and interosseous membrane are completely torn. In

doubtful cases x-ray films of the normal ankle in plantar flexion and dorsiflexion compared with those of the injured ankle may be of aid. The normal amount of widening when the foot is dorsiflexed should be kept in mind.

TREATMENT

Treatment of rupture of the tibiofibular ligaments and diastasis should be based on anatomic and physiologic considerations, taking into account the normal motions at the tibiofibular joint. The importance of early recognition and treatment cannot be overestimated. Apfelbach and Boim² in 300 films of ankle fractures noted diastasis in 40 per cent at the time of injury, whereas widening of the mortise was observed in 94 per cent as a clinical end result.

It must be kept in mind that not only widening of the ankle mortise but anteroposterior instability of the distal end of the fibula may result if diastasis is not recognized and properly treated. If normal motions and ankle joint stability are to be preserved, early accurate reduction must be carried out and maintained until the ligaments and the associated fractures have healed.

In the presence of definite tibiofibular diastasis the tibia and fibula may be reapproximated readily, pro-

Fig. 6.—Gatellier's approach to posterior tibial marginal fracture. Indicated when closed reduction is unsuccessful and when there is complete rupture of the tibiofibular ligaments. In addition, the internal malleolus may be approached through a separate medial incision if necessary.

vided there is no interposition of soft tissue or bone. When difficulty is encountered in effecting reduction, interposition is usually found to be the cause. Organized clot may give the same effect in late cases. Operation should be resorted to without hesitation under these

circumstances and the interposed substance removed or accurately replaced. The approach is made through a short incision over the anterior aspect of the tibiofibular joint. If difficulty is encountered in holding the fibula in its place well against the tibia, a screw or wire may be inserted through a small incision on the lateral aspect of the fibula.

The question of the routine use of metal fixation of the fibula to the tibia is one that has not been definitely settled. Undoubtedly it may facilitate the handling of these cases in some instances. One may cause fractures of the internal malleolus with gross displacement to reassume readily the normal relation to the tibia simply by reducing the diastasis and adequately maintaining reduction by the use of a screw. Removal of the metal fixation should be carried out in every case as soon as the ruptured ligaments have healed. Failure to do so usually results in the loss of dorsiflexion because motions of the fibula are prevented when it is fixed to the tibia.

The position in which the foot is immobilized after reduction has been effected is of importance whether internal fixation is used or not. It has already been brought out in this study that separation of the mortise after the ligaments are divided takes place when on

Fig. 7.—A, tibiofibular diastasis, fracture in the lower fourth of the fibula, fracture of internal malleolus and posterior tibial marginal fracture. Closed reduction unsuccessful. B, after operation. Gatellier's approach used. Tibiofibular screws should always be removed when union has occurred.

dorsiflexion the foot reaches 90 degrees. The position of choice for postreduction immobilization then is slight plantar flexion, the position which eliminates any tendency for separation of the two bones. This should also be kept in mind in cases in which there is a posterior marginal fracture of the tibia, as the usual position of fixation in dorsiflexion may at the same time cause separation of the fibula from the tibia.

In certain cases of diastasis associated with Pott's fracture and posterior tibial marginal fracture in which the fibula is broken two or three inches above the ankle joint, Gatellier's³ approach has been found to be very satisfactory. This method is used when, for some reason or other, the posterior tibial fragment cannot be brought down into normal position. A lateral peroneal approach is made and the peroneal tendon retracted forward. The distal end of the fibula is freed and reflected downward, the external lateral ligaments acting as a hinge. The posterior tibial fragment is accurately reduced and fixed with screws. The fibula is then replaced and fixed with screws and the peroneal tendons are brought back into their normal positions.

ABSTRACT OF DISCUSSION

DR. CLAY RAY MURRAY, New York: Dr. Alldredge's paper has presented clearly a frequent problem in ankle fractures which is often overlooked with resultant disability. Disruption of the inferior tibiofibular joint is a common complication of high fractures of the lower fibula and a frequent enough complication of other ankle fractures. It is usually a far more serious lesion than any of the associated fractures from the standpoint of difficulty of treatment as well as resultant disability. Treatment of it does not enter into consideration in many cases because its presence is not recognized. Often the discovery of a widened mortise, an unstable ankle and a secondarily stiff and painful joint due to traumatic arthritis is made in a follow-up examination many months after the original injury. He has outlined clearly the important points in the diagnosis of this condition. It should be looked for and eliminated as a possibility in all ankle fractures before treatment for the fracture is instituted. Its common occurrence is one of the best arguments I know of against the marked inversion of the foot so commonly practiced in the immobilization of ankle fractures, since it is with marked inversion or eversion of the foot that x-ray examination most clearly demonstrates the diastasis of the tibiofibular joint. With proper x-ray examination using, as Dr. Alldredge suggests, a position (among others) which gives an anteroposterior view of the ankle with the foot in eversion or pronation (Dr. Alldredge refers to it as external rotation), the diastasis when present can be clearly shown. Marked inversion or supination of the foot will produce the same result. It is obvious then that any marked eversion or inversion of the foot as a position of fixation is a sure way to maintain the diastasis. When reduction is delayed in these cases, clotting of hemorrhage and exudate in the widened joint space may prevent reduction by closed methods, and interposition of ligamentous tissue or bone fragments may have the same effect. Failure to correct the diastasis is revealed in the postreduction x-ray films if they are taken in accordance with the directions given in Dr. Alldredge's paper. In the event of such failure, operative measures are indicated. When no such interposition exists, which is in the majority of cases, the reduction must, in addition to replacing bone fragments, firmly compress tibia against fibula at the tibiofibular joint, and the fixation must maintain this compression not only until such time as the ligaments have healed but until the healing has become strong enough to stand the strain of dorsiflexion of the foot. Where the diastasis has been rather easily recognized, full weight bearing on these ankles, even though the x-ray films may appear perfectly satisfactory, should be delayed for from twelve to sixteen weeks from the time of injury.

DR. GEORGE O. EATON, Baltimore: Dr. Alldredge is to be congratulated on emphasizing the presence and the importance of a tibiofibular diastasis. There is one point that I feel like complaining about. Dr. Alldredge states that fluoroscopic examination of the ankle is probably not as accurate as x-ray films. I think this is an understatement of fact. I think it is a deplorable habit to depend on fluoroscopic examinations as the x-ray diagnosis of fractures. If a fracture is present one should have x-ray films not only as a permanent record but also as a guide in attacking the problem of reducing the fracture. If the injury to the ankle is a fracture or a fracture without displacement, more often than not it will be missed if dependence is placed on fluoroscopic examination. As regards the posterior tibial marginal fracture, by far the majority of these marginal fractures are less than 30 per cent of the tibial plafond, and conservative treatment in addition to the reduction of the other fractures present can be depended on to yield a good result. Dr. Alldredge's paper is certainly excellent and timely and the literature, as he stated, is scarce on this important subject.

DR. RUFUS H. ALLDREDGE, New Orleans: I tried to stress the treatment of these ankle joint injuries with especial reference to the normal physiologic motions of the fibula. I have also tried to summarize the diagnostic points. As far as the use of the fluoroscope is concerned, in contrast to examination of

carefully taken x-ray films, I can only say that I think in most cases one can make a diagnosis from the x-ray film if one knows what to look for in the way of abnormalities. In posterior marginal fracture of the tibia, unless it is large enough to cause disturbance in function later or unless it is associated with fracture of the lower third of the fibula, together with rupture of the tibiofibular ligaments, it is not necessary to use the radical approach as it can be exposed simply through a posterior incision on the medial aspect of the achilles tendon.

MILKERS' NODULES

FREDERIC T. BECKER, M.D.

DULUTH, MINN.

The opportunity to observe and study four cases of milkers' nodules during the summer of 1939, and my inability to find in the American literature any description of this disease, prompt this report. This is an occupational infection of milkers which may be widely distributed among the dairying communities of our country. It is my purpose to give a clinical description of milkers' nodules and differentiate this disorder from other diseases occurring on the hands of milkers, and discuss the cause, pathology and immunology.

The initial lesions may vary from one to forty in number and they are usually located on the hands and fingers. The incubation period is from five to seven days after contact with a diseased cow, and the infection enters the human skin through abrasions. At the onset an erythematous papule develops, which slowly increases in size, becoming a firm, elastic, bluish red nodule from 1 to 2 cm. in diameter. The lesions may be surrounded by an inflammatory areola and may be found in various stages of development. The nodule becomes semiglobular with a central depression; the surface becomes flat, and when the grayish loose epidermal covering is removed a reddened, granulating base remains. The nodule itself gives rise to few subjective symptoms, only slight pain and mild itching. As healing progresses the entire nodule flattens and the granulation tissue is absorbed; involution becomes complete in from four to six weeks without scar formation. The regional glands are occasionally enlarged and secondary pyogenic infection with lymphangitis may occur. There is little constitutional reaction except in unusual instances, when the eruption becomes generalized or secondary infection ensues.

According to Kummer¹ there have been twelve reports in which a generalized eruption has occurred. These disseminated lesions are multiform in type, being either umbilicated papules, urticarial wheals or macules, any of which may become vesicular or hemorrhagic. This generalized outbreak subsides within a week, and the eruption has been considered as being either toxic or produced by hematogenous dissemination of the infection.

All cases of milkers' nodules have occurred in people employed as milkers of cows on whose udders crusted or ulcerated lesions were found to be present. All cases have developed in the latter part of the summer. One

attack apparently leaves immunity, since we have been unable to ascertain any instance of a recurrence. Most veterinarians have diagnosed the lesions which were present on the cows as being similar to those of cowpox.

DIFFERENTIAL DIAGNOSIS

European investigators differentiate milkers' nodules from other conditions many of which would seldom offer confusion in this country. Symmetrical tylosa of Arzt² consists of bilateral calluses located on the knuckles of both thumbs in persons using the Swiss method of milking. Jadassohn³ described inflammatory nodules which are produced by cow hair entering calluses or fissures. Continental authors also consider hoof and mouth disease in differentiation, but the absence of oral lesions and systemic reaction in milkers' nodules should be sufficient to avoid confusion. In exceptional cases, when the eruption becomes generalized, erythema multiforme might be considered. I considered pyogenic granuloma when I saw my first case, but history of contact with an infected cow, the spontaneous resolution of the nodule, and microscopic examination were diagnostic criteria. The relation to vaccinia will be discussed with the consideration of the cause.

ETIOLOGY AND REVIEW OF THE LITERATURE

The majority of investigators think a virus is the infectious agent. Its relation to cowpox has led to much controversy. Winternitz,⁴ who described the first case of milkers' nodules in 1899, was uncertain about the cause. Frieboes⁵ in 1914 reported a case and inoculated the material into a scarified rabbit's cornea with negative results. He supported cowpox as the cause because the cattle which had been the source of the infection were considered to have this disease by the veterinarians. Paschen⁶ made an extensive review of the literature and was of the opinion that cowpox and milkers' nodules could be sharply separated. He stated that in a disease caused by a pox virus a positive Paul's⁷ test⁸ should be obtained and in all individuals who were infected, either human beings or experimental animals, should be immune to later vaccination with vaccine virus. He was unable to come to any definite conclusion but suggested that the disease was a result of an infection of milkers with vaccine virus which was attenuated by a secondary invader.

Schultze, Seifried, and Schaaf⁹ were among the first investigators able to demonstrate experimentally any relation to vaccinia. They studied twenty cases in various stages of development and by inoculating material from the nodules into calves were able to produce lesions similar to cowpox. Their experimental animals as well as the human patients proved resistant to vaccination with cowpox and reinoculation with a filtrate from

milkers' nodules. These workers also obtained positive Paul's tests in which they demonstrated Guarnieri bodies and they believed that the repeated trauma associated with the occupation of milking favored the development of nodules in some persons rather than the typical vesicopustules of vaccinia.

Stark and his co-workers¹⁰ published an account of experimental and clinical investigation of an epidemic occurring in packing house workers who handled sheep. After repeated animal transfers they were able to produce pox lesions in which they could demonstrate inclusion bodies. These authors believed that their observations spoke for the identity of the virus of milkers' nodules with that of variola vaccine, the former undergoing alteration in its biologic properties by parasitism in foreign hosts, the original properties being recovered by repeated animal transfers.

Gottron¹¹ vaccinated a cow with material from a nodule and produced a papulopustular eruption which was indistinguishable from cowpox; however, he obtained a reinfection in the same animal with pox virus eight weeks later. Tappeiner¹² in his case obtained a positive Paul's test in which Guarnieri bodies could be demonstrated, but the reaction took five days instead of the usual two. He and Gottron were of the opinion that the virus of milkers' nodules was less virulent than that of cowpox.

Many of the recent workers have considered the paravaccine of Lipschutz¹³ as the etiologic agent. Lipschutz found that some people when vaccinated develop a dark red papule instead of the usual vesicopustular reaction. In these lesions he was able to find gram negative inclusion bodies. The infection could be transmitted to animals and human beings but those infected showed no immunity to vaccinia. He also found the virus both of vaccinia and of paravaccinia present in the same calf lymph; the latter, however, did not produce a positive Paul reaction. The microscopic and immunologic studies in paravaccinia as described by Lipschutz resemble those found in milkers' nodules.

Dolgov and Morosov,¹⁴ Zenin,¹⁵ Falchi¹⁶ and Bonnevie,¹⁷ after reviewing the literature and studying their cases, considered the cause of milkers' nodules to be a virus similar to variola vaccine and believe "paravaccine of Lipschutz" the most likely. They based their conclusion on the variation in the pathology of variola and milkers' nodules, the lack of immunity to vaccination with cowpox, and the absence of pustulation in milkers' nodules, which healed spontaneously without scar formation.

Groth,¹⁸ Kaiser and Gherardini¹⁹ and Woringe²⁰ stated that they were unable to make any definite

conclusions as the result of their observations, but they found little evidence to favor vaccine virus as a cause of milkers' nodules.

Histologic interpretations of biopsy specimens of milkers' nodules depend on the age of the lesions. Schultze, Seifried and Schaaf, Woringe and Bonnevie found that in an early lesion there was acanthosis and reticular degeneration²¹ of the upper cells of the malpighian layer with formation of microscopic multilocular vesicles. Considerable edema of the papillae and corium developed with vascular and lymph vessel dilatation accompanied by an infiltration with various cells, of which eosinophils were prominent. Later parakeratosis and hyperkeratosis were present and in the corium granulation tissue developed. Bonnevie found that the histologic changes in upper layers of the epidermis resembled the reticular degenerative changes seen in variola except that the multilocular vesicles that were formed in milkers' nodules remain microscopic. The hyperkeratosis present probably prevented the vesicles from becoming larger or reaching the surface. The exudate in the epidermal vesicles of milkers' nodules

Fig. 1 (case 2).—Typical milkers' nodule with two secondary lesions. Photographed by Dr. R. H. Puumala.

however, in contrast to variola, does not become pustular, and the dermis of the nodules is characterized by the formation of granulation tissue.

REPORT OF CASES

CASE 1.—S. N., a white youth aged 16 years, had never been vaccinated for smallpox. He spent his summer vacation on a farm, where he milked cows that had "crusted sores" on their udders. A small dark red pea sized papule developed between the first and second fingers of the right hand. The lesion slowly grew larger until it became the size of a cherry. At the end of three weeks he consulted his local physician, who described the lesion as a semisolid brownish red nodule 1 cm. in diameter which was covered by a dried grayish epidermis, which he easily removed. The patient was referred to me and examination showed a nodule 0.75 cm. in diameter of red granulation tissue. One right axillary gland was enlarged to the size of a walnut and was slightly tender. My first diagnostic impression was pyogenic granuloma. However, the unusual history of contact with sores on cattle prompted the performance of a biopsy, after which the remainder of the nodule was cauterized. Healing was uneventful and took place

21. Unna (Die Histopathologie der Hautkrankheiten, Berlin, A. Hirschwald, 1894) described reticular degeneration as a vacuolar deterioration of the cells of the upper rete malpighii producing large clear cells in which some of the cellular membranes rupture, producing multilocular vesicles.

within ten days. The patient was vaccinated two weeks after the lesion healed; a positive reaction developed which produced a typical scar.

CASE 2.—J. H., a patient of Dr. R. H. Puumala of Cloquet, Minn., a white youth aged 18 years, was never vaccinated and had milked cows on his father's farm for the past nine years.

Fig. 2.—Low power magnification of section from case 2 showing hyperkeratosis, multilocular vesicles and dense cellular infiltrate in the dermis; stained with hematoxylin-eosin.

In June 1939 he first noticed that some of the cows developed crusts on their udders. About the middle of August a small papule developed at the site of a scratch on the medial surface of the first finger of the left hand; this lesion slowly grew larger and four days later two others started on the dorso-lateral aspect of the right wrist and thumb. My examination on August 28 showed a hard, nonpainful, brownish red nodule on the left index finger, 1 cm. in diameter and 4 mm. high. The top surface was slightly delled. The lesions on the right hand were pea sized papules with a small central vesicle. Both right and left epitrochlear glands were enlarged to about the size of a hazelnut and two axillary glands were the size of a walnut and slightly tender. A punch biopsy was taken of the first lesion on the left index finger. Half of the material was emulsified and some of it was instilled into the scarified cornea of two rabbits and the rest was injected into the skin and foot pads of two guinea pigs. The other half was placed in solution of formaldehyde, embedded in paraffin, sectioned and stained with hematoxylin and eosin. All lesions were dressed with sterile petrolatum and observed every other day by Dr. Puumala, who reported that the lesions were entirely healed in one month without any scar except at the site of the biopsy wound. At this time he vaccinated the patient with smallpox vaccine, which produced a positive reaction that resulted in the classic scar.

CASE 3.²²—Mrs. M. W., a white woman aged 27, seen Sept. 1, 1939, milked cows at irregular intervals during the past year and stated that one of the animals had sores about the udder. Three weeks previous to the time of consultation she noticed a lesion on the right thumb which continued to grow. Examination showed a round, bluish red button-like tumor 1.5 cm. in diameter on the first joint of the right thumb. The center was slightly depressed and whitish. There were no palpable enlarged lymph nodes. The nodule was removed and divided in half; one portion was fixed in solution of

formaldehyde and sectioned and stained with hematoxylin and eosin. The other part was emulsified and some of it instilled in the scarified cornea of a rabbit and the rest injected into the thigh and skin of two guinea pigs.

CASE 4.—Mrs. L. W., a farmer's wife aged 28, observed Sept. 29, 1939, stated that she developed about three weeks previously an eruption on the right little finger. Examination revealed an elevated bluish red semisolid tumor 1 cm. in diameter on the right little finger. The top surface of the growth was easily removed, leaving a red granulating surface. A biopsy was taken and the lesion cauterized, after which uneventful healing took place.

EXPERIMENTAL RESULTS

The corneas of all rabbits inoculated with material in cases 2 and 3 were watched daily for a period of two weeks and no reaction took place and the corneas remained clear. The guinea pigs were kept under observation for two months. No inflammatory reaction occurred at the injection sites. They were killed at this time and no evidence of any infection could be found at pathologic examination. Cultures were made on all types of routine mediums with the emulsified material from cases 2 and 3 and no growth was obtained.

HISTOLOGY

The microscopic examinations in my four cases were similar to those described in the literature and the essential features which I found may be summarized as follows:

There was considerable increase in the stratum corneum with hyperkeratosis and parakeratosis (fig. 2). Acanthosis and spongiosis were present and in the upper layers of the rete malpighii there was an increased intracellular edema which produced in some scattered

Fig. 3.—High power reproduction of figure 2, showing the dermis with dense multicellular infiltrate and marked blood vessel dilatation.

areas enlarged clear cells with only a thin cellular membrane and in other areas there were microscopic multilocular vesicles. The dermis was edematous with an increased vascularity (fig. 3) and dense cellular infiltration was present which disrupted the epidermal-dermal junction. This infiltrate was made up principally of

²² Cases 3 and 4 were observed by Dr. Stephen Epstein of Marshfield, Wis., and are recorded with his permission. The biopsy material was studied by me.

lymphocytes and also many plasma cells, eosinophils and an occasional giant cell and polymorphonuclear leukocyte. The increased intracellular edema with the formation of microscopic multilocular vesicles could be interpreted as a mild degree of reticular degeneration as described by Unna. In none of the microscopic sections studied was there any evidence of pustulation.

COMMENT

It is quite evident both clinically and histologically that the lesions occurring in the four cases described are similar in nature to those recorded in the German literature as "melkerknoten." All individuals afflicted had been engaged in milking cows on whose udders open ulcers or crusted lesions had been present. The cause of milkers' nodules is undoubtedly infectious, because the condition is self limited, healing spontaneously without treatment and apparently leaving an immunity to further similar inoculations. My inability to demonstrate any bacteria both by culture and by animal inoculation, plus the fact that many investigators have found inclusion bodies in a microscopic section, would indicate that the infecting agent is a filtrable virus.

The relation of this virus to vaccinia is still in a controversial state. The first to show any definite relation between the two were Schultze, Seifried and Schaaf. Paschen and Groth, however, believed that these cases were vaccinia and not true milkers' nodules. Experimental work of Stark and his co-workers supported the theory that the organism of milkers' nodules was of decreased virulence because only after repeated transfers to the same species of animals were they able to show conclusive evidence that the virus had the characteristics of variola vaccine.

It is generally agreed that for a virus to be similar to that of variola a positive Paul test must be obtained and the individual infected should acquire an immunity against vaccine virus. The majority of investigators of milkers' nodules have been unable to obtain positive Paul reactions from their cases and most of their patients have not acquired any immunity to smallpox vaccine. My results of a negative Paul test in two of the cases and a lack of immunity to vaccination as demonstrated in two others agrees with most authors. Therefore, because of these two facts along with the difference in the histologic picture and in the clinical course of milkers' nodules there does not seem to be much evidence to support any relation to variola vaccine. On the other hand, the pathologic process of milkers' nodules seems to show a close similarity to paravaccinia, as neither of the disorders produces immunity to subsequent inoculation with vaccine virus, the Paul test is negative and the microscopic appearances are similar in the two instances.

SUMMARY

1. Four cases of milkers' nodules, which is an infection of human beings acquired by milking diseased cows, were observed.
2. No relation between milkers' nodules and vaccinia could be demonstrated in these cases, as the Paul test, which was performed with material from two cases, was negative and two of the infected persons showed no immunity to smallpox vaccination.
3. The clinical course of milkers' nodules and the distinct variations in the pathologic picture are further evidences that this disease shows no relation to variola vaccine.

4. The cause of milkers' nodules is apparently a virus, which may be either an attenuated or biologic modification of vaccine virus. From all evidence it more closely resembles the paravaccine of Lipschutz.

205 West Second Street.

ABSTRACT OF DISCUSSION

DR. M. E. OBERMAYER, Chicago: Dr. Becker's presentation is thorough and complete, and it answers a long-felt need. In the United States, large sections of which are agricultural, an occupational disease among milkers is bound to be far more widespread than is indicated by the scarcity of case reports. There is still a great deal of controversy concerning the etiologic agents of the disorder. The only point on which the various investigators agree is that the condition is undoubtedly caused by a filtrable virus. In regard to the nature of the virus there are three schools of thought: (1) that the virus of milkers' nodules is identical with that of vaccinia, (2) that the virus of milkers' nodules represents an attenuated or biologically modified vaccinia virus or (3) that the virus of milkers' nodules has nothing to do with that of vaccinia but is identical with the virus of paravaccinia of Lipschutz. From what Dr. Becker said and from some additional references it seems that the evidence gathered for each of the three points of view is sufficiently strong to substantiate the choice of virus assumed to be responsible in each particular case which was studied. If to prove the identity of the virus of milkers' nodules with that of vaccinia three criteria must be met, namely (a) a positive Paul test, (b) demonstration of Guarnieri bodies and (c) failure to produce a positive take in the patient by ordinary antimallpox vaccination, satisfactory proof has been obtained though only in a small number of instances. The second assumption, that the virus represents an attenuated or biologically modified vaccinia virus, has been substantiated by the properties which the virus has exhibited after repeated animal transfers. The results of Dr. Becker's study led him to conclude that the third theory about the etiologic agent, supported by the evidence from his own cases, is the most acceptable. When reviewing the experimental data critically, I feel that the evidence which has been presented in favor of each of the three suggestions need not necessarily be considered conflicting if it is assumed that milkers' nodules represent a clinical entity caused by filtrable viruses of different kinds. The disorder may be caused at times by the ordinary virus of vaccinia, more often by an attenuated or biologically altered vaccinia virus and frequently by the virus of paravaccinia. The fact that the viruses of vaccinia and of paravaccinia have been found simultaneously in the same lymph is suggestive. Moreover, there seems to be evidence that the clinical aspects of the disease on the udders of the animals are not uniform. Thus the assumption of multiple etiologic agents of the disorder seems to me a logical means of bringing the seemingly conflicting evidence into agreement.

DR. C. GUY LANE, Boston: This condition is relatively unusual. The photograph which was shown on the screen was made last fall of these two lesions of three weeks' duration. The lesions presented themselves within two or three days after this man started working on a farm milking cows. He had not done this work for some twenty years previously. He noticed small erosions first, at the sites of friction between his fore and middle fingers following the beginning of his new job of milking. Then there was gradual development at the sites of the lesions which were shown on the screen. There were vesicles at the start, blisters that became eroded and then gradually became elevated. In one axilla there were one or two palpable tender glands. Our cultures at the hospital showed only staphylococci. The interpretation of the biopsy was at that time simply chronic inflammatory reaction. There is nothing known in this particular case with reference to the condition of the cow. The lesion subsided relatively readily under mild antiseptic therapy. It is interesting to review these cases and analyze our reasons for deciding that these are occupational. In the first place they occur so far as we know only in the agricultural occupations, those having to do with animals. The lesions are consistent with those which have previously been described in the literature

The time relationship is correct since this condition appears relatively few days after the patient has begun the job. Again, their site of onset is the site of the maximum trauma, or the site of the particular trauma, where greatest friction occurs, and as far as is known at present there is no other known source of this infection.

DR. FREDERIC T. BECKER, Duluth, Minn.: From the contact I have had in the Scientific Exhibit, I am sure that milkers' nodules are not rare in this country. Many doctors who are located in dairying communities have seen these cases at intervals. I think that calling attention to it will bring forth many new cases.

TROPHIC LESIONS IN THE DISTRIBUTION OF THE TRIGEMINAL NERVE

LOUIS J. KARNOSH, M.D.
CLEVELAND

AND

ROGER F. SCHERB, M.D.
CAMARILLO, CALIF.

To the neurologist, bona fide trophic changes are lesions appearing in tissues which have been deprived of certain qualities of sensation, particularly those of pain and temperature.

That portion of the face which is supplied by the trigeminal nerve may be thus denervated by a number of organic disturbances. The neurosurgeon accomplishes this by sectioning the nerve through its peripheral branches, the gasserian ganglion, the posterior root or, more selectively, by the newest procedure devised by Sjöqvist,¹ namely cutting the descending spinal tract in the medulla.

Occasionally a tumor or an inflammatory process may be so peculiarly situated near the ganglion or in the brain stem as to interrupt the sensory function and cause some degree of anesthesia in the face. Most striking is the analgesia produced by two well known lesions of the medulla, namely occlusion of the posterior inferior cerebellar artery and syringobulbia.

The whole subject of trigeminal nerve function has undergone a recent renaissance and a wealth of literature has emerged, representative of which are the studies of Sjöqvist;¹ Walker;² Rowbotham;³ Smyth⁴ and Lewy, Groff and Grant.⁵ In all these discourses little is said of neurotrophic lesions in the trigeminal area for the reason that such disturbances are rather rare. This, of course, is true only if one excludes the simple herpetic eruptions about the lips which occur in many febrile diseases and if one also makes an exception of the corneal complications following section of the trigeminal nerve. The more malignant herpes which is associated with persistent neuralgia is of uncommon occurrence. Peet⁶ found only three cases among 400

sufferers with facial neuralgia and quoted Frazier as having encountered but one instance in 520 cases, while Cushing mentioned herpetic neuralgia in only three of 332 operations on the gasserian ganglion.

This discussion concerns itself with trophic lesions which are nonherpetic in nature. The three examples which are presented have all been studied by competent dermatologists, who found no explanation for the appearance of the lesions except on a neurotrophic basis. These cutaneous phenomena have these features in common: They are implanted on areas definitely devoid of pain and temperature sense and they all conform sharply to neuroanatomic delineations. They differ in that the interruption of sensation occurs at different levels in the trigeminal system: In the first case the changes in the skin followed a gasserian section, in the second case it is clinically assumed that the disturbance was caused by an occlusion of the posterior inferior cerebellar artery, and in the third case the symptoms were typical of syringobulbia.

DERMATITIS FOLLOWING GASSERIAN SECTION

Simple erythematous eruptions following trigeminal nerve section are unusual, unpredictable and puzzling phenomena. In a review of 107 cases in which the ganglion or the posterior root was cut, Becker⁷ was able to find only five cases in which cutaneous manifestations were presented. He himself reported the case of a 47 year old woman who developed an erythematovesicular eruption, which appeared three weeks after an operation for trigeminal neuralgia.

The following case, of a cutaneous disturbance previously reported by Netherton⁸ from the point of view of a dermatologist, is now reviewed after further study of the process and its relation to the neural defect:

CASE 1.—A woman aged 44 came to the Cleveland Clinic in March 1930 for relief from paroxysmal facial neuralgia, characterized by a hot, jagging pain over the left side of about five years' duration. The attacks were induced by rubbing the upper or lower eyelid and by talking or chewing.

Nothing of significance was elicited from her history except that she had occasional attacks of urticaria and a mild eczema had developed in the flexor regions of the extremities.

Surgical treatment consisted of a total section of the first and second divisions and a partial section of the third division of the trigeminal nerve. A year later an erythematous plaque developed on the left side of the forehead, to be quickly followed by similar lesions over the left temple, the lower lip, the left cheek and the left side of the nose. The areas gradually became confluent, and a sharp line of demarcation between normal and abnormal skin developed in the middle of the face. The erythematous flush was particularly prominent in the areas supplied by the first and second divisions of the severed trigeminal nerve and faded diffusely into the zone of the third division.

Neurologic examination disclosed marked hypesthesia to all qualities of sensation in the areas supplied by the ophthalmic and mandibular divisions and total anesthesia in the area assigned to the second division. There was typical absence of the corneal reflex on the affected side, but no evidence of involvement of the sympathetic nerves. Thermocouple readings were similar on the two sides of the face.

The cutaneous disturbance remained strictly unilateral in distribution. It was not accompanied by pain or other subjective disturbances. There was no induration of the underlying tissues. Exposure to cold, heat, wind, soap and water produced periodic exacerbations of an exudative inflammation, followed by increased desquamation.

All this embarrassed the patient greatly and handicapped her in business. She managed a meat stall in a large open market. Would-be customers glanced at her facial blemish and passed on to trade with her competitors. Despite various topical applications, the condition remains essentially unimproved at the present time. Biopsy of the skin was not allowed.

In attempting to explain the relation of eczema to nerve injury such as is here presented, dermatologists can offer only an empiric opinion. Bruck⁹ expressed the belief that many skin eruptions of this nature may be of true neural origin, but only when the damage is limited to the somatic sensory fibers while the sympathetic and vasomotor mechanisms are intact. Such an explanation, however, is inadequate, for this very situation obtains in almost every case of neuralgia following trigeminal nerve section and yet eczema rarely follows. The preexisting allergy may be significant, and the singular disposition to eczema in other parts of the body must be considered as a factor in determining this unusual reaction to facial hemianesthesia.

TROPHIC CHANGES FOLLOWING THROMBOSIS OF THE POSTERIOR INFERIOR CEREBELLAR ARTERY

Bruck's theory is even less tenable in explaining trophic changes which occur on the face after an occlusion of the posterior inferior cerebellar artery, for not only is there marked analgesia of the homolateral

CASE 2.—A white man aged 48, a glazier, was suffering with diabetes, which was well controlled by 5 units of insulin before each meal. On the morning of Nov. 9, 1934, he was awakened by a peculiar sensation of numbness over the entire left side of the face and a deep, gnawing, burning pain about the left eye. On rubbing his face he found the right side to be moist with perspiration and the left side utterly dry. On

Fig. 2 (case 2).—Distribution of trophic lesions and of analgesia due to vascular softening of the lateral portion of the medulla following an occlusion of the posterior inferior cerebellar artery. Both ulceration and analgesia conform to the peripheral orientation of the trigeminal nerve. The area supplied by the geniculate portion of the facial nerve is spared.

Fig. 1 (case 2).—Appearance of lesions.

side of the face but the sympathetic and vasomotor fibers are frequently involved in the same destructive process. Irrespective of the damage to the vegetative nerve components, the cutaneous changes may become extensive and pernicious and may cause severe distortion of the tissues of the face.

attaining the sitting position in bed he became very dizzy and on attempting to stand he swayed strongly to the left.

The neurologic components of significance were as follows: The pupils were unequal, the left being very small and reacting slightly to the flashlight. There was a clockwise rotatory nystagmus when the gaze was directed to the left. The left corneal reflex was absent. The greater portion of the left trigeminal area was analgesic, while tactile sense was only moderately impaired. The sensory defect was pronounced in those areas in which the patient experienced the deep pain; that is, at the root of the nose and just under the left eye. The left side of the palate was poorly elevated. Excursion of the vocal cords was symmetrical. The left abdominal and cremasteric reflexes were absent. In the Romberg test the patient swayed violently to the left side.

The ulcers appeared about six weeks after the onset of the illness as small red patches at the left angle of the mouth, under the left eye and on the left side of the nose. These were entirely painless and gradually spread, leaving in their wake a reddened, puffy, indurated, crusted skin, which broke down again and again until there was considerable deformity of the face. Lesions appeared in the scalp, anterior to the ear and on the chin but never outside the left trigeminal area. Biopsy of the skin demonstrated no specific disease.

These distressing cutaneous changes on the left side of the face were accompanied by a Horner syndrome. There was a marked difference in the temperature of the skin on the two sides of the face. The Minor starch and iodine test, according to the technic outlined by List and Peet,¹⁰ demonstrated com-

plete paralysis of sweating on the left side. A resection of the inferior cervical ganglion was done with the hope that by further increasing the blood supply the cutaneous lesions would improve. The procedure merely served to increase the enophthalmos. To roentgen therapy the response was equally indifferent.

At the present time the trophic process has advanced into the eyeball, the cornea being cloudy and showing extensive vascularization in its lower segments. The conjunctiva and all periorbital tissues are markedly edematous.

The trophic disease in this case appears to be in direct proportion to the degree of analgesia, the most severe lesions being found in the first and second divisions of the trigeminal area (figs. 1 and 2). The skin supplied by the mandibular division is only moderately analgesic, and the trophic changes are minimal. The nature and distribution of the skin eruptions are

objective testimony that the descending spinal tract of the trigeminal nerve is fundamentally arranged to conform to the peripheral distribution of the nerve, a finding about which there is general agreement.

TROPHIC LESIONS IN SYRINGOBULBIA

No concerted opinion exists, however, with respect to the significance of the sensory changes which may occur in syringobulbia. Such tangible evidence of sensory loss as trophic ulceration of the face is usually wanting in this medullary disease. It is true that hyperostosis of the facial bones has been noted in syringobulbia, and in 1930 Thomas¹³ described a case in which there was thickening of the left side of the face, but trophic changes in the skin itself are not mentioned in any clinical reports on this disease.

CASE 3.—A stocky white woman aged 37 first noticed numbness of the left hand and shoulder and the left side of the face five years before she came to the attention of the neurologic clinic at the City Hospital. The numbness of the face was more irritating than painful. She applied a heat lamp to the area, and quickly there developed shallow, painless ulcers about the left ear. These extended directly upward into the scalp and downward along the angle of the jaw.

The positive observations in the neurologic examination were as follows: The left corneal reflex was absent and there was a rotating type of nystagmus, more pronounced when the gaze was directed to the left. The gag reflex was absent on the left side, and the left vocal cord was inactive during phonation. The posture was stooped, with a thoracic kyphosis. There was slight atrophy of the muscles of both shoulder girdles, more marked on the right side. In the left hand the thenar eminence was small; in the right hand there was considerable atrophy of the interosseous tissues.

The sensory examination revealed anesthesia to pain and temperature on the left side of the head, limited anteriorly by a line passing from the vertex downward over the malar prominence to the angle of the jaw. This area of total analgesia extended backward into the scalp and downward over the neck and in mantle-like fashion over both shoulders to the elbows and the nipple levels of the chest. In the face, anterior to the analgesic zone, was a narrow band of hypalgesia, while the area about the nose, mouth and eye was essentially normal in pain and temperature sense. Tactile sense was well preserved everywhere, demonstrating the familiar dissociation of sense characteristic of syringomyelia. There was no involvement of the sympathetic nervous system.

The facial lesions appeared in the area which is supplied by overlapping branches of the trigeminal and the highest cervical nerves. The erosions spread, healed occasionally with a thick epithelial covering, only to reopen and increase in size. They eventually extended deep into the external auditory meatus. After many sporadic attempts at healing, a progressive induration ensued, leading to considerable cicatrization, particularly below the ear.

In this case the disposition of ulcers furnishes objective evidence of the peculiar nature of the sensory disturbances which occur in the trigeminal area in syringobulbia. Both the trophic ulceration and the sensory changes utterly ignore the peripheral orientation of the fifth nerve and dispose themselves in a segmental or concentric fashion converging on the nose and mouth (figs. 3 and 4). The erosions are equally heedless of the sensory architecture about the ear, involving the geniculate or facial components about the external auditory meatus and showing no regard for the peripheral topography of the auricular and occipital branches of the cervical plexus.

The concentric sensory zoning on the face is not an uncommon occurrence in syringobulbia and is observed

Fig. 3 (case 3).—Trophic ulcers and sensory defect in a case of syringobulbia.

in harmony with most of the descriptions of sensory change in the Wallenberg syndrome. Moreover, an identical sensory disturbance was found by Sjöqvist¹ and Walker² and by Grant, Groff and Lewy¹¹ in patients after tractotomy, so that one is fairly certain that this patient had a lesion in the descending spinal tract. Not only do the lesions orient themselves in their intensity according to the three peripheral divisions of the fifth nerve but both ulcerations and analgesia avoid the area assigned by Ramsay Hunt¹² to the sensory portion of the facial nerve. Whatever the pathologic process may be, this trophic change in a disease of the lateral portion of the medulla offers

in no other disease. Schlesinger¹⁴ in 1895 and von Sölder¹⁵ in 1899 noted that loss of pain sense first appeared in the scalp and advanced toward the nose and mouth. Dejerine¹⁶ made the same observation and came to the conclusion that the trigeminal structures in the brain stem are segmentally arranged in terms of concentric circles converging on the nose. Woods¹⁷ supported the same hypothesis after reporting two cases of syringobulbia. We investigated three cases of this disease and in only one was this type of sensory disturbance absent. Yet Taylor, Greenfield and Martin¹⁸ and Jonesco-Sisesti¹⁹ did not agree that this segmentation of pain sense is typical of syringobulbia. After making excellent clinicopathologic correlations, Smyth⁴ ridiculed this concept of concentric zoning, although he conceded that it may be occasionally encountered. For this he had no explanation. Perhaps, as Sjöqvist suggested, this sensory disturbance is peculiar to syringo-

clearly known, and his proof that it is not segmentally arranged is not very convincing.

In the case presented here the trophic erosions of the skin are so disposed as to support the theory that this tract conveying pain and temperature sensations across the medulla retains its primitive lamellar or segmental arrangement in the same manner as does its homologue in the spinal cord, namely the spinothalamic tract. That the latter structure, which is equally susceptible to syringomyelia, possesses this anatomic feature has been demonstrated in the clinical investigations of Tilney and Elsberg²⁰ and by the neurosurgical studies of Hyndman and Van Epps.²¹

SUMMARY

Neurotrophic changes in the trigeminal area of a nonherpetic type may occur in any disease which destroys the fibers conveying pain and temperature sense. That they are uncommon is probably due to the fact that the face is instinctively better protected from trauma than are other parts of the body which become analgesic. The erosive process on the skin can exist independent of sympathetic involvement. Skin eruptions of a trophic nature may arise as unpredictable and embarrassing sequelae of nerve section for facial neuralgia.

Destructive lesions of the brain stem produce trophic disorders the distribution of which offers additional data as to the manner in which the fibers of the trigeminal pathways are arranged within the central nervous system. Vascular softenings which usually involve the lateral portions of the medulla produce sensory changes which conform to the peripheral distribution of the trigeminal nerve, while a process which primarily destroys the inner structures of the brain stem leads to analgesic areas with a concentric zoning converging on the nose and mouth.

ABSTRACT OF DISCUSSION

DR. MAX MINOR PEET, Ann Arbor, Mich.: I have no explanation for these trophic disturbances or diseases involving the trigeminal tract. I have seen three cases of apparent trophic disturbance in about 1,000 operations for section of the sensory root of the gasserian ganglion. Three tenths of 1 per cent is a very small incidence. In two of those cases there were rather marked paresthesias. This is a peculiar sensory disturbance when the face itself is absolutely anesthetic. The patient feels crawling or burning sensations and itching or tickling and more or less constantly traumatizes his face. One of these patients—and they all were elderly—constantly rubbed the nose or picked it, and I think possibly that was the cause of the disturbance. Both of these elderly persons who had this type of lesion had a slow, almost benign, ulceration starting in the ala of the nose, and it finally went to complete destruction of the lower corner of the ala and then extended slowly, gradually, over a number of years, out to the adjacent part of the cheek. The ulceration was exceedingly superficial. It would be healed much of the time and then break out again apparently under direct trauma. The patients both said they had these paresthesias, that they couldn't help picking at the nose or face, and they both thought this constant trauma was a factor. The third case developed in the ophthalmic division in the forehead. The patient came back several years after operation with typical whitish scars in the forehead, such as are seen after a true herpes, and I am not certain whether this patient actually developed a true herpetic lesion superimposed on an anesthetic area following section of the sensory root. In the last patient that had this destruc-

Fig. 4 (case 3).—Peripheral nerve topography is ignored, and the lesions of the skin as well as the analgesic areas are arranged in a concentric manner, with the zones converging on the nose and mouth.

bulbia because the disease primarily involves the second sensory neuron of the trigeminal nerve, the so-called quintothalamic tract. In its orderly ascent through the reticular portion of the brain stem the pathologic process exposed the segmental structure of this tract and its nucleus. It is conceivable that the irregular sensory disturbances observed by some writers are produced by a process which destroys parts of both the first and the second sensory neuron. Smyth admitted that the anatomic position of the quintothalamic tract is not

tion of the ala of the nose I had our dermatology department study the patient. There were no signs of malignancy. There were semicutaneous changes in other parts of the face and body and the dermatology department didn't want to say whether this was trophic, whether this was actually in any way related to section of the sensory root of the gasserian ganglion or whether it was a traumatic lesion incident to the paresthesia that the patient was suffering. It seems that, if we are going to assume that these are trophic, they ought to occur in a much higher percentage of cases. We know the very high incidence of herpes which occurs after operation. For a long time I assumed that these herpetic manifestations were due to injury directly to the gasserian ganglion incident to its exposure. I do not take up the ganglion, of course, but strip the dura from it. Then on one patient I sectioned the sensory root by the posterior approach. I was nowhere near the ganglion, I could not have disturbed it, and that individual had the most extensive herpetic lesions on the lower half of the face of any patient I have ever seen. So it is not due to direct trauma to the gasserian ganglion.

DR. A. EARL WALKER, Chicago: In view of the fact that the denervated areas are commonly said to be particularly susceptible to infection and injury, it is remarkable that following retrogasserian neurectomy so few cases such as have been described today are reported. From France in 1936 Dechaume and Delibéros (*Rev. de stomatol.* 38:194 [March] 1936) reported an ulcerative lesion of the maxillary mucous membrane of a patient who, twelve years before, had a retrogasserian neurectomy. They stated that such a complication was unique in their experience. In their case trauma was probably a precipitating factor, as Dr. Peet has emphasized, for the patient had worn an ill fitting denture which bothered her a great deal. I am more interested in the type of sensory disturbance which the authors have discussed. It has been shown that section of the descending root of the trigeminal nerve, in the manner Sjöqvist devised, produces sensory changes, a marked analgesia with relative hypesthesia in the divisional portions of the face; that is, it involves the first, second or third division but does not give rise to the onion skin type of sensory disturbance which is seen occasionally in syringobulbia. Neuro-anatomy does not tell the reason for this difference, although it has now been shown that there is a definite laminar arrangement of the tracts derived from both the nucleus of the descending portion of the trigeminal nerve and the main trigeminal nucleus. The onion skin type of sensory disturbance is analogous to the stocking or glove type of sensory disturbances in the arms or legs. We know that such sensory disturbances do not usually occur with spinal cord lesions, but they are seen with lesions of the thalamus and cerebral cortex. This suggests that there is a rearrangement of the nerve fibers in their passage from the spinal cord to the thalamus and to the cortex. It is quite probable that such a rearrangement of the fibers occurs very shortly after their origin in the spinal cord or from the descending root in the fifth nerve. Hence, as Sjöqvist, Smyth, Stratford and others have suggested, syringobulbia involving the secondary trigeminal pathways would give rise to the type of sensory disturbance which is more commonly seen with lesions of the thalamus or cerebral cortex than the type of impairment which is seen with section of the primary sensory nerve fiber.

DR. BYRON STOOKEY, New York: I should like to confirm what Dr. Peet said. In a large series of trigeminal operations I have not encountered the type of lesions presented to us this morning. The only trophic disturbances, if they are trophic disturbances, that I have seen have been the ones Dr. Peet has described following the operation immediately, and then there has been another group of which I should think there are about seven or eight cases of so-called seborrheic dermatitis, a scaly, greasy condition found over the distribution of the fifth nerve, mostly in the first division, to a less extent in the second division, in those instances in which we have done a total section. With these two exceptions I have not encountered the type of lesion which has been presented. I am extremely interested in the presentation. I question whether we can call it trophic disturbances and I wondered, in view of the extreme rarity of the lesions following dorsal section, if they are necessarily alone to be attributed to the cutting of the fifth nerve root.

MELANOMA OF THE CENTRAL NERVOUS SYSTEM

REPORT OF THIRTY-FOUR CASES, IN NINETEEN OF WHICH THE DIAGNOSIS WAS VERIFIED BY OPERATION OR NECROPSY

FREDERICK P. MOERSCH, M.D.

J. GRAFTON LOVE, M.D.

AND

JAMES W. KERNOHAN, M.D.

ROCHESTER, MINN.

During the five weeks from April 1 to May 5, 1939, inclusive, we had occasion to make a diagnosis of melanoma of the central nervous system in four cases. The rapid succession of these four tragic experiences prompted us to carry out the present study.

A survey of the literature on melanoma reveals an almost endless list of contributions covering various phases of the subject. In this presentation we are not concerned with the histologic structure of melanoma but wish to stress the importance of melanoma from the neurologic standpoint. We are employing the terms "melanoma," "melanocarcinoma," "melanosarcoma" and "melano-epithelioma" synonymously.

That melanomas are a serious menace to life needs no comment. The frequency of their occurrence remains somewhat uncertain. Adair¹ reported that 400 cases were observed at the Memorial Hospital in Chicago during an eighteen year period. In 41,984 surgical specimens examined by the department of pathology at the Toronto General Hospital from January 1928 to January 1935 Plewes² found ninety-three melanomas, or an incidence of 0.2 per cent. Affleck,³ in a follow-up study of 170 patients who had melanomas, found that 115 died in less than three years and that 10 per cent were alive after a lapse of five years. Broders and MacCarty⁴ in their review said that the mortality rate was 86.8 per cent although they said that all their patients had not been heard from.

Two contributions on melanomas of the nervous system, one by the Wortises⁵ in 1936 and the other by Courville and Schillinger⁶ in 1939, leave little to be added to the general consideration of the subject. It may be well, however, again to call attention to the frequency with which melanomas involve the central nervous system and to urge rigid prophylaxis against this disease. As Adair has stated, "there is no tumor which places the clinician in such a mental state of helplessness as the melanoma once it has left the original site." The frequency with which melanomas metastasize to the central nervous system varies from 10 to 50 per cent according to different authors. In a series of 20,000 necropsies Courville and Schillinger noted twenty instances of melanoma; in eighteen of the cases there

was widespread metastasis. In nine, or 50 per cent, of the eighteen cases, the brain was involved. Bailey⁷ suggested a similar figure for involvement of the brain in the presence of generalized metastasis. He stated, however, that this figure may be somewhat high. In 1932 Dunlap,⁸ in a report of ninety-five metastatic tumors of the brain observed at the Mayo Clinic, said that he found only two melanomas. As a result of our present study this figure should be increased by several cases. In a series of 107 cases of metastatic tumor of the brain, Courville and Schillinger observed that the incidence of melanomas was 13 per cent.

MATERIAL

In the ten year period from 1930 to 1939 inclusive we have seen approximately 500 cases of melanoma. This number represents about 2 per cent of the total number of cases of malignant lesions seen during that period. Unfortunately a complete follow-up study in the 500 cases has not been possible; therefore accurate deductions cannot be made. In approximately a fourth of the cases of melanoma the primary tumor was situated in or about the eye. In at least 347 of the 500 cases there was evidence of local recurrence or metastasis at the time the patients were last seen at the clinic. The majority of these patients have died. In at least thirty-four, or 10 per cent, of the 347 cases there was clinical evidence of melanotic involvement of the central nervous system.

CLINICAL AND PATHOLOGIC CONSIDERATION

In twenty-four cases the brain was the site of the melanomic involvement. In ten cases the spinal cord was affected. In one instance both the brain and the spinal cord were affected. In nineteen of the thirty-four cases the diagnosis was verified by microscopic examination of a specimen removed from the brain or spinal cord at operation or by necropsy (table 1). In the remaining fifteen cases necropsy was not performed or did not include examination of the central nervous system. However, biopsy disclosed that the primary tumor was a melanoma; clinical signs and symptoms were indicative of involvement of the central nervous system and there usually was evidence of generalized metastasis. We have excluded from this study twenty-four additional cases which with but a slight stretch of the imagination might well be included in this category but, because of the absence of postmortem or operative confirmation, must be excluded. It does seem proper to call attention to this additional group because in a study of this type one cannot fail to be impressed by the fact that metastatic involvement of the central nervous system by melanomas is much more common than is generally appreciated. If these twenty-four cases had been included it would have been found that the central nervous system was involved in 20 per cent of the cases of melanoma in which generalized metastasis had occurred. This incidence is less than half of that reported by Courville and Schillinger and by Bailey. This difference may be attributable to our inability to obtain accurate follow-up data.

There are several good reasons for the failure to appreciate the importance of melanotic involvement of the central nervous system. Following a diagnosis of melanoma with evidence of metastases, the patient is frequently taken home and dies without a postmortem examination. Again, in the absence of a primary

melanoma of the skin or in some other obvious site a patient may die without a proper diagnosis and the correct diagnosis may be established only by necropsy, which is performed only occasionally (Plewes). The very late occurrence of metastasis from a primary melanoma may also lead to an incorrect diagnosis. In our series of cases the correct diagnosis would have been overlooked in at least twelve instances had the patient failed to come to operation or necropsy. From these statements it must be appreciated that the statistics on the involvement of the central nervous system by melanoma are rather inaccurate. Twelve of the thirty-four patients died while under observation at the clinic; in ten of the twelve cases necropsy was performed. Seventeen patients died at home; necropsy was performed in four of these cases. The remaining five patients could not be followed.

Of the thirty-four patients, twenty-three were males and eleven were females. Twenty-nine patients are known to be dead and in five cases follow-up data were not available. Necropsy was performed in fourteen of the twenty-nine cases in which death is known to have occurred. In seven of the fourteen cases necropsy was not complete, and in another case, in which necropsy was performed at the patient's home, no mention was made of postmortem examination of the brain or spinal cord. In three of the seven cases neither the brain nor the spinal cord was examined at necropsy and in four cases examination of one of these structures was omitted. Operation was performed in eleven cases, in six for tumor of the brain and in five for tumor of the spinal cord. It is noteworthy that in twelve cases the presence of a melanoma was not suspected prior to operation or necropsy. In eight of the twelve cases no primary melanoma was discovered. In three cases, after the melanoma in the nervous system was found the patient or the family revealed that a mole had been removed previously. In the remaining case the eye had been enucleated some time previously. A diagnosis of glaucoma had been made but because of the subsequent course of events the eye undoubtedly must be considered as the site of a primary melanoma. This group of twelve cases indicates the need of constantly bearing in mind the possibility of a melanoma in the presence of a rapidly progressive disorder of the central nervous system. Great care must also be exercised in the examination of patients suspected of having melanoma and whenever possible any available material should be submitted for microscopic examination.

The ages of the patients at the time of examination at the clinic because of symptoms referable to the central nervous system ranged from 4 years to 66 years. Twenty-two of the thirty-four patients were in the fourth to the sixth decade of life inclusive. The length of time from the excision of the primary melanoma or mole to the death of the patient varied from four months to thirteen years. The average duration was approximately two and a half years. As far as we could determine, the majority of the primary moles had been removed surgically but the mole had been removed some time after evidence of rapid growth had developed. It is pertinent to this problem to insist that moles situated in places subject to irritation should be excised before they show any signs of "wildness." The site of the known primary mole was as follows: back, ten cases; head, face and neck, five cases; eyes, six cases; heel, two cases; hand, one case; umbilicus, one case; labium, one case, and unknown, eight cases. From our studies no definite statement can be made concerning

TABLE 1.—*Clinical and Postmortem Data in Thirty-Four Cases of Melanoma of the Central Nervous System*

Case and Sex	Age, Years		Site of Primary Mole	Duration of Neurologic Symptoms Before Visit to Clinic	Clinical Diagnosis	Neurologic Symptoms	Clinical Course	Postmortem Observations	Comment
	When Mole Was Excised	At Death							
1 ♂	39	40	Neck	2½ weeks	Metastatic melanoma of brain	Headache, diplopia and progressive delirium for 2½ weeks; no papilledema	Died 5 days after registration	Multiple melanomas of brain; largest tumor in left temporal lobe; generalized metastasis to organs of body	
2 ♂	..	61	Back	2 months	Melanoma not suspected	Mental confusion and progressive weakness for 2 months; terminal coma; papilledema	Died 3 days after registration	Brain not examined; melanoma in spinal meninges; generalized metastasis to organs of body	Mole not discovered until after death
3 ♀	33	36 (?)	Back	4 months	Metastatic melanoma of brain	Headache, weakness and confusion for 4 months; papilledema of 3-4 diopters	Returned home after operation; condition became progressively worse; no final information	Operation disclosed melanoma of left frontal lobe
4 ♂	62	63	Heel	6 weeks	Metastatic melanoma of brain	Dizziness, vomiting and ataxia for 6 weeks; terminal stupor; no papilledema	Died 2 weeks after registration	Multiple melanomas of cerebrum and cerebellum; spinal cord was not examined; generalized metastasis to organs of body	
5 ♂	41	43	Eyelid	6 months	Melanoma not suspected	Deafness, headache, vomiting and ataxia for 6 weeks; no papilledema	Returned home and died 1 year later	Operation disclosed melanoma of left frontal lobe; mole on eyelid was not recorded in history
6 ♂	..	55	?	1 day	Melanoma not suspected	Left hemiplegia developed gradually 10 days after an exploratory laparotomy	Patient died of cerebral thrombosis (?) 10 days after operation	Multiple melanomas in cortex and ventricles; generalized metastasis to organs of body; site of primary tumor unknown	Exploratory laparotomy disclosed a melanoma
7 ♀	37	?	?	8 months	Melanoma not suspected	Fatigue, headache, falling vision, incoordination and mental dulness for 8 months; papilledema of 5 diopters	Died one day after craniotomy	One large melanoma of left frontal lobe; primary in brain (?); no melanomas in other organs	
8 ♂	..	49	?	7 months	Melanoma not suspected	Signs and symptoms of compression of spinal cord at first thoracic segment for 7 months	Returned home and died 2 months later	Laminectomy and biopsy disclosed a melanoma
9 ♂	38	41	Back	2 months	Melanoma not suspected	Numbness of right arm for 2 months; this was followed by jacksonian convulsions; coma for 4 days before death	Patient died of bronchopneumonia 24 hours after admission	Melanoma (5 cm.) in left parietal lobe; ependymoma of fourth ventricle; melanomas in other organs	History of primary mole not obtained until after necropsy
10 ♂	..	34	?	8 years (?)	Melanoma not suspected	Hemangioma of the cervical segment of the spinal cord suspected and exploratory operation performed 9 months before patient came to clinic; symptoms had progressed; no spinal subarachnoid block; examination of spinal fluid disclosed 50 mg. of protein per 100 cc. and 56 lymphocytes per cubic millimeter	Patient died at home	Another exploratory operation on cervical segment of spinal cord disclosed a melanoma; 4 months later an exploratory laparotomy at home revealed multiple melanomas
11 ♂	..	31	?	2½ months	Melanoma not suspected	Increasing headache, blurred vision and syncope attacks for 2½ months; papilledema of 4 to 6 diopters; no localizing signs	Died 1 day following exploratory craniotomy	Large melanoma of third ventricle, which extended to the fourth ventricle, pons and medulla; only the head examined	
12 ♂	66	67	Eye	3 months(?)	Metastatic melanoma of brain	Headache and weakness following enucleation of eye for melanoma; local recurrence of the tumor; no neurologic examination	Died 2 days after admission	Melanoma of right occipital lobe; extension to arachnoid and dura; generalized metastasis to organs of body	
13 ♂	17	19	Neck	4 months	Metastatic melanoma of brain	Headache, spells of unconsciousness and diplopia for 4 months; papilledema of 5 to 6 diopters	Condition became worse after patient went home; patient died 6 months later	Melanoma removed from left frontal lobe
14 ♂	..	63	?	4 years	Melanoma not suspected	History of progressive lesion of spinal cord for 4 years; partial spinal subarachnoid block; 100 mg. of protein per 100 cc. of spinal fluid	Was alive 2 years after operation; final follow-up data not obtained	Laminectomy and biopsy disclosed a melanoma
15 ♀	..	55	?	3 years	Melanoma not suspected	History of progressive compression of spinal cord at level of fifth thoracic segment; complete spinal subarachnoid block; 1,200 mg. of protein per 100 cc. of spinal fluid	Condition of patient was critical 4 months after she returned home	Laminectomy and biopsy disclosed a melanoma
16 ♀	..	16	?	6 weeks	Melanoma not suspected	Headache, vomiting and papilledema of 4 to 5 diopters for 6 weeks	Died 1 year later at home	Exploratory operation and biopsy disclosed melanoma of cerebellum
17 ♀	40	44	Umbilicus	5 months	Metastatic melanoma of brain	Headache, mental cloudiness and spells of unconsciousness for 5 months; no papilledema	Returned home and died 10 days later	Single melanoma, 3 cm. in diameter, in left parietal lobe; spinal cord not examined; no pathologic report of melanomas in other parts of body	Biopsy at home had revealed that mole was benign; biopsy of lymph node disclosed melanoma

TABLE 1.—Clinical and Postmortem Data in Thirty-Four Cases of Melanoma of the Central Nervous System—Continued

Case and Sex	Age, Years		Site of Primary Mole	Duration of Neurologic Symptoms Before Visit to Clinic	Clinical Diagnosis	Neurologic Symptoms	Clinical Course	Postmortem Observations	Comment
	When Mole Was Excised	At Death							
18 ♂	55	56	Eye	3 months	Metastatic tumor of spinal cord and brain (?)	Eye had been enucleated 9 months previously for glaucoma (?); no pathologic examination; severe facial pain with anesthesia for previous 3 months; signs of compression of spinal cord for 6 weeks; partial spinal subarachnoid block; spinal fluid yellow; 1,600 mg. of protein per 100 cc. of spinal fluid	Returned home and died 3 months later	Generalized melanomas in organs of body; brain and spinal cord not examined	Laminectomy and biopsy disclosed a melanoma
19 ♂	32	33	Eye	6 weeks	Melanoma not suspected	Eye had been enucleated 1 year previously; no pathologic examination; general weakness, absence of knee jerks and attacks of coma for 6 weeks	Condition gradually became worse; patient died 3 weeks after registration	Multiple small melanomas of meninges and bones of skull; generalized metastasis to organs of body	
20 ♂	37	44	Conjunctiva	6 weeks	Metastatic melanoma of brain (?)	Headache, vertigo, incoordination and mental cloudiness for 6 weeks; papilledema; roentgenogram of thorax disclosed metastatic lesions	Returned home and died 2 weeks later	Course of roentgen therapy to head
21 ♀	54	59	Heel	5 months	Metastatic melanoma of brain (?)	Progressive mental change, weakness of left side and left homonymous hemianopia for 6 months	Returned home and died 1 month later	No treatment at clinic
22 ♂	49	55	Scalp	6 weeks	Metastatic melanoma of brain (?)	Progressive weakness of left arm for 6 weeks; blurred vision and vomiting occurred later	Follow-up data not available	No treatment at clinic; 3 small melanomas on left choroid
23 ♂	42	45	Back	3 months	Metastatic melanoma of spinal cord (?)	Lumbar root pain for 3 months; transverse myelitis	Returned home and died 3 months later	Symptomatic treatment
24 ♂	61	63	Nose	3 weeks	Melanoma of spinal cord (?)	Increasing back pain and progressive weakness for 3 weeks	Returned home and died 3 months later	Generalized melanoma of organs of body; vertebral column and spinal nerves involved; brain and spinal cord not examined	Symptomatic treatment at clinic
25 ♀	14	24	Back	3 months	Metastatic melanoma of brain (?)	History of headache; increasing confusion, choked disks and coma for 3 months	Died 2 days after registration	
26 ♂	42	43	Back	6 weeks	Melanoma of spinal cord (?)	Increasing numbness and weakness of legs for 6 weeks	Returned home and died 6 weeks later; transverse myelitis	No treatment at clinic
27 ♀	4	4	Eye	2 months	Metastatic tumor of brain (?)	Enlargement of globe of left eye for several months; enucleation of eye; headache and pain in legs developed later	Mass developed on occiput; patient failed gradually and died at home 2 months after registration	Radium applied to left orbit
28 ♂	52	53	Back	4 weeks	Metastatic melanoma of brain (?)	Headache, progressive aphasia and weakness for 4 weeks; roentgenogram of thorax suggested metastatic involvement	Patient returned home; no follow-up data	No treatment at clinic
29 ♀	45	46	Labia	4 weeks	Metastatic melanoma of brain (?)	Progressive aphasia and generalized weakness for 4 weeks; coma	Died following symptomatic treatment for 2 weeks	
30 ♀	50	54	Back	6 months	Metastatic melanoma of spinal cord (?)	Progressive weakness of left arm for 6 months; roentgenograms disclosed metastatic involvement of thorax and spinal column	Returned home and died 3 months later	No treatment at clinic
31 ♂	60	63	Thumb	6 months	Metastatic melanoma of spinal cord (?)	Progressive back pain with extension to scatic region for 6 months; roentgenogram showed metastatic involvement of sacrum	Returned home and died 6 months later	No treatment at clinic
32 ♂	40	41	Face	5 weeks	Metastatic melanoma of brain (?)	Progressive weakness of left arm for 5 weeks; several jacksonian convulsions; metastatic involvement of thorax	Progressive coma and death	Generalized metastasis to organs of body; brain and spinal cord not examined	
33 ♀	25	27	Back	7 weeks	Metastatic melanoma of brain (?)	Increasing headache, diplopia and vomiting for 7 weeks; rigidity of neck; choked disks of 4 to 5 diopters; metastatic involvement of thorax	Patient returned home and died 4 weeks (?) later	No treatment at clinic
34 ♂	25	35	Back	Metastatic melanoma of brain (?)	Mole removed from back 1 year before registration; generalized melanin pigmentation for 2½ months; melanin in urine	Returned home; had several convulsions; died 4 months later	Necropsy at home; generalized metastasis but no statement about central nervous system	Lead treatment

the presence of other moles. The length of the time the mole was present before removal varied from one to thirty-eight years. A few patients stated that the mole had always been present. As a rule some fourteen months had elapsed between the removal of the initial mole and the first signs of metastasis. Unfortunately we have no definite information regarding the many moles which may have been removed without development of metastases at some later date. As can be seen from table 1, a fair percentage of our patients apparently had an involvement of the central nervous system by melanoma prior to involvement of the other organs of the body. If organs other than the central nervous system were involved first, subsequent involvement of the central nervous system, if it did develop, usually occurred in about two months. In four of the thirty-four cases the primary melanoma occurred in the choroid of the eye. It is interesting to note that during the ten year period under consideration there have been observed at the clinic 125 cases of melanoma of the eye in which enucleation was performed either here or elsewhere. Strangely enough, our figures are not in keeping with those of some of the other writers who maintain that melanoma of the eye is especially prone to metastasize to the central nervous system. Had we been able to obtain follow-up data in the entire group of 125 cases of melanoma of the eye we probably would

TABLE 2.—Results of Examination of Cerebrospinal Fluid in Five Cases of Melanoma of the Spinal Cord

have discovered more than four instances of involvement of the central nervous system, but apparently the percentage is relatively small. Our observations are in keeping with those of Benedict,⁹ who said that melanoma of the choroid tends to metastasize to other organs of the body, especially the liver, in preference to the central nervous system. Terry and Johns,¹⁰ in a review of ninety-eight cases of melanoma of the eye, noted that the diagnosis was incorrect in forty-two instances. The diagnosis in these forty-two cases was glaucoma, opaque cornea, inflammatory lesion and so on and the correct diagnosis was made only by biopsy.

In only one of the thirty-four cases in our series was there metastatic involvement of both the brain and the spinal cord. In three cases the melanoma appeared to be primary in the brain and in three cases it appeared to be primary in the spinal cord. In these six cases operation was performed and the diagnosis of melanoma was made by biopsy. Four of the six patients are known to have died. A complete necropsy was possible in one case and partial necropsy was performed in another case. Two of the six patients were alive at the time the last follow-up data were obtained. In none of these six cases did any signs of metastasis develop. In the case in which complete necropsy was possible the primary melanoma undoubtedly involved the central nervous system. In the other five cases (one of which was reported previously by one of us¹¹) the available data certainly suggested that the primary melanoma involved the central nervous system.

In eleven of the twenty-four cases of melanoma of the brain the outstanding clinical symptoms, such as mental dulness, confusion, coma and delirium, pointed to involvement of the brain. As emphasized by Craig and one of us¹² the neurologic diagnosis may present various difficulties because of the mental status of the patient and the diffuse character of the symptoms. In two cases the clinical picture was confused by the presence of a bromide psychosis or drug intoxication. Several of the patients were moribund when they were brought to the hospital and the correct diagnosis was made only at necropsy. The cerebrospinal fluid was examined in three cases of melanoma of the brain. In two cases the fluid was entirely normal. In the remaining case the value for the total protein was 50 mg. per hundred cubic centimeters of fluid and there were sixty-seven lymphocytes in each cubic centimeter of fluid. The results of examination of the cerebrospinal fluid in five cases of melanoma of the spinal cord are shown in table 2. In no instance was melanin discovered in the spinal fluid.

Roentgenographic examination of the skull was of little value in the diagnosis of melanoma of the brain. In five instances roentgenographic examination of the thorax showed evidence of metastatic involvement and in two additional cases the results of such examination were suggestive of metastatic involvement. Contrary to the usual statement concerning involvement of the bone, we have seen melanotic erosion of the vertebrae, the sacrum and the skull in three cases. Nine of the thirty-four patients showed clinical signs of generalized metastasis when examined at the clinic. Loss of weight was a common symptom. In five cases the sedimentation rates of the erythrocytes were 10, 18, 24, 64 and 109 mm. at the end of one hour, respectively. In only one instance was melanin discovered in the urine, but tests for melanin in the urine were not carried out as a routine in this series of cases.

At times a melanoma may be associated with an acoustic neuroma.¹³ Björneboe¹⁴ has observed the association of melanoma with von Recklinghausen's disease. Occasionally, diffuse melanosis of the skin as reported by Odel and his co-workers¹⁵ (fig. 1) will give the clue to the correct diagnosis. Space will not permit of a lengthy consideration of the individual cases, each one of which presented some interesting diagnostic and clinical problem. The clinical and pathologic data in these cases are shown in table 1.

COMMENT

In considering melanomas it must be emphasized that the frequency of their occurrence in the central nervous system is much greater than is generally recognized. While metastasis usually occurs within a few years after removal of the primary melanoma, as many as ten or even twenty-five years may elapse between removal of a primary melanoma and metastatic involvement of the central nervous system or of other organs of the body. This late development of metastatic melanoma must be kept in mind in any statistical study, for undoubtedly many patients who have melanoma die years after the

removal of the primary mole or melanoma with an incorrect diagnosis. It is of considerable interest, as noted by Knight,¹⁶ Adair and others, that a patient with a melanoma of the eye may survive enucleation of the eye for many years and when metastasis does occur it tends to occur elsewhere than in the central nervous system, especially in the liver. The incidence of metastasis to the central nervous system from melanomas of the eye has been unusually rare in our series of cases as compared to that reported in the literature. One reason for the apparent good prognosis in cases of melanoma of the eye is that the lesion is recognized rather early as a result of the disturbance of vision and the melanoma is removed before extension or metastasis occurs.

It is evident from a survey of our postmortem material that metastatic melanoma may occur throughout the organs of the body without involvement of the central

when a middle-aged person has a rapidly progressing mental or nervous disease and the usual conditions such as vascular disease, inflammatory affliction may be ruled out, it is important to consider seriously the possibility of melanoma of the central nervous system.

Fig. 1.—Diffuse melanosis of skin.

nervous system, and, similarly though to a lesser degree, the brain or spinal cord may be the only site of metastatic involvement.

As noted by Courville and Schillinger, Plewes and others, involvement of bony structures by melanoma has been comparatively rare. When it has occurred it invariably has resulted from direct extension of the melanotic growth. In an appreciable number of cases we have witnessed involvement of the brachial plexus and lumbosacral plexus by melanotic extension or by metastasis.

In the differential diagnosis of melanoma it must be remembered that the patient or relatives frequently will fail to mention the previous removal of a mole. As a rule, such information is withheld unintentionally but in a few cases in our series the knowledge of a mole was deliberately withheld because of the previous unfavorable prognosis. As has been emphasized by Bailey,

Fig. 2.—Melanoma of brain.

Although at present there seems little that can be accomplished by operation in cases of melanoma of the central nervous system, one should not adopt a defeatist attitude with regard to this serious affliction. In a small percentage of cases a great deal of palliative relief, even if not actual cure, can be obtained by radical operation. If the melanoma is primary in a so-called silent area of the brain, radical surgical removal may be justified; if the lesion is single and nodular, even though metastatic, complete removal may be possible. If the lesion cannot be extirpated from the brain (fig. 2) a palliative subtemporal decompression may afford relief from the increased intracranial pressure and its consequent headache, vomiting and failing vision.

If the melanoma is intraspinal and does not invade the spinal medulla (fig. 3), complete removal is pos-

Fig. 3.—Melanoma of spinal cord.

sible. Even if it involves one or more nerve roots, these might be sacrificed in a radical surgical procedure without endangering the patient's life. If the spinal cord or intraspinal nerve roots are involved by a neoplasm, and if the tumor is not too extensive, a subtotal removal is not only justifiable but definitely indicated to ameliorate the patient's symptoms.

16. Knight, Mary S.: Melanotic Neoplasms of the Eye, J. A. M. A. 83:1062-1068 (Oct. 4) 1924.

We do not wish to enter into a discussion of the microscopic appearance of melanomas, but there are several points worth considering. It is generally considered by pathologists that nonpigmented or sparsely pigmented melanomas are more malignant than those deeply laden with pigment. When a nonpigmented melanoma is found by the neurosurgeon it is very difficult for him or the pathologist to identify the origin of such a tumor. The melanin content of many of these neoplasms varies from one region to the next and at times it varies in degree in the same metastatic nodule.

These tumors may spread either by blood stream or by lymphatics and usually by both; the original tumors have a tendency to invade blood spaces early and this explains their wide dissemination throughout the body. It is difficult to understand why in some cases there may be a latent period of many years between the excision of the original tumor and the appearance of the secondary masses. This late recurrence of metastasis is misleading and disconcerting to all concerned in dealing with the problem.

It has been shown in a sufficient number of instances that melanomas arise primarily from the meninges. Before one can accept such a case one must be certain that no small primary skin tumor has been overlooked and that there is no metastasis to other organs. The latter requirement is at times extremely difficult to fulfill on clinical and roentgenologic grounds alone, and without a thorough search at necropsy such a case should be accepted with reservation. In six cases in our series we were of the opinion that the tumors occurred primarily in the central nervous system but because of lack of necropsy we can only say that they possibly originated in the meninges. We were able to prove to our own satisfaction that one tumor was primary in the central nervous system.

CONCLUSIONS

1. Melanoma of the central nervous system is a diagnosis that must be reckoned with by the neurologist.
2. Careful inquiry about the removal of pigmented lesions should be carried out and, if possible, any available material should be reexamined for the presence of melanoma.
3. It must be realized that a melanoma occasionally may be primary in the central nervous system and that in the presence of any rapidly progressive lesion of the central nervous system such a diagnosis must be seriously considered.
4. While it is not in the realm of the neurologist to advise patients regarding lesions of the skin, the opportunity of preaching prophylaxis in the presence of pigmented moles must not be overlooked.

ABSTRACT OF DISCUSSION

DR. S. BERNARD WORTIS, New York: Dr. Moersch and his associates have emphasized the serious nature of melanoma of the central nervous system. Some years ago we reported several from the Bellevue Hospital and can only confirm the observations of Dr. Moersch and his group. Our patients were all over 50 years of age. Papilledema was common. In some of our patients the cerebrospinal fluid was bloody and in a few we were able to find melanin pigment or melanin cells in the spinal fluid. One point worthy of emphasis is that the time between the onset of original irritation of the melanotic focus and the onset of cerebral symptoms varies from eight to ten years, whereas the time elapsing from the onset of cerebral symptoms to death is much shorter, in our series from seven days to two or three months. Many of the symptoms are those referable to disseminated lesions in the nervous sys-

tem simulating diffuse meningo-encephalopathy. Since a third of all melanomas originate in the choroid of the eye, a syndrome can be established wherein one can distinguish four clinicopathologic stages in the course of such tumors. The first stage consists of detachment of the retina by the melanotic tumor and is associated with impairment of vision, a defect in the visual field or complete blindness of one eye. The second stage consists of the period of increasing intra-ocular tension associated with pain. This condition of the eye often resembles glaucoma. However, it can be differentiated from glaucoma by the fact that melanomasarcoma is preceded by blindness and the patient subsequently has pain. In glaucoma pain comes first and blindness is a subsequent occurrence. Subsequent stages give evidence of diffuse involvement of other organs. When the liver is involved in these people the urine gives a positive test for melanuria. I agree with Dr. Moersch and his group that these people require early treatment of the primary focus, and this caution cannot be overemphasized.

DR. PETER BASSOE, Chicago: A man whom I saw when he was 40 years old was known to have had syphilis, had been treated for many years and had become Wassermann negative and was in perfect health until two weeks before I saw him, when he was taken with headache and vomiting, followed by a convulsion and aphasic disturbance. A lumbar puncture was made. The Wassermann reaction was negative with spinal fluid and blood. A few days after the onset I was told that his eyegrounds had been examined in the morning and found normal. In the evening of the same day there were hemorrhages in both eyes; and when I saw him there was a marked papilledema with hemorrhages. We disregarded the syphilitic history and made a diagnosis of tumor of the brain. The patient lived only a few days. Autopsy revealed a large melanotic tumor on the left side, which accounted for the focal symptoms and two other similar tumors which confirm Dr. Moersch's statement that nothing can be done surgically with these tumors. Aside from the vomiting, which undoubtedly was due to the brain lesion, this man had never had anything to call attention to his abdomen. The autopsy, which was complete, showed that the primary tumor was a melanotic carcinoma of the pancreas.

DR. HANS H. REESE, Madison, Wis.: I believe that melanoma belongs to the large group of von Bogaert's congenital neuroectodermal dysplasias: (1) tuberose sclerosis, (2) neurofibromatosis of von Recklinghausen, (3) angiomas and (4) ectodermal dystrophies (xeroderma idiocy, hereditary familial keratoses, congenital generalized ichthyosis). I wish to ask the authors whether or not they considered the melanoma as a subdivision of the status pigmentatus. Von Bogaert of Antwerp is correct in assuming that the various groups are one and the same group but with different tissue selectivity. If the tissue selectivity occurs in the form of a skin melanoma there may be a disturbance in the melanin and iron containing pigment distribution; therefore a radical surgical intervention would remove only a localized metabolic dysplasia of the melanic pigment. I can't see any reason to interfere surgically with a skin lesion. I do not know whether the authors meant that all primary melanomas should be operated on early. Clinical observation reveals that melanomas grow or metastasize with rapidity on intervention. One cannot make the diagnosis of generalized tissue melanoma. Do you consider a melanoma as being a melanomasarcoma or do you regard a localized melanoma only as a specific pigment accumulation in the ectoderm? The various infiltrations of leukemia or of xanthoma do not cure the basic disturbances even if localized lesions are removed. Do you know whether any spectrolytic observations are known which support an early diagnosis of suspected melanoma and which would eliminate a biopsy? Did you find in your post-mortem examinations any increased pigmentations in the globus pallidus, rubra zone, substantia nigra and locus coeruleus? I should like Dr. Moersch to answer the question How do you treat a localized melanoma especially in view of the high probability of metastases?

DR. FREDERICK P. MOERSCH, Rochester, Minn.: The remarks of Dr. Wortis regarding melanoma of the eye are well taken. It is interesting how frequently melanomas of the eye will

metastasize to the liver and not to the brain. As Dr. Bassoe pointed out, many of these patients come in with a very short history. As a matter of fact, some of our patients were brought into the hospital in a state of coma, and not until postmortem examination was the melanoma discovered. In the paper I purposely avoided the possibilities that Dr. Reese suggested because I believe it becomes an exceedingly controversial subject as to what one man considers a melanoma and what is considered melanoma by another. I am sorry Dr. Kernohan is not here to answer the questions of Dr. Reese. I am sorry I cannot.

A PREPARATION OF TOXIN SUITABLE FOR ORAL IMMUNIZATION AGAINST SCARLET FEVER

GEORGE F. DICK, M.D.

AND

GLADYS HENRY DICK, M.D.

CHICAGO

That sterile scarlet fever toxin administered by mouth may result in satisfactory immunization was reported in 1932.¹ This observation was first made during attempts to learn whether or not some of the so-called intestinal rashes mentioned as occurring in children might be caused by milk which had been contaminated with a scarlet fever streptococcus and subsequently pasteurized at a temperature which kills the streptococci but does not destroy the toxin.

In these first experiments it was found that transient scarlatinal rashes might occur in susceptible persons when comparatively large doses of the sterile toxin were ingested. Subsequent cutaneous tests showed modification of the susceptibility, indicating the production of some degree of antitoxic immunity.

This observation led to further experiments in which sterile toxin, containing 0.5 per cent phenol, was administered by mouth in graduated doses. The results indicated that, if enough toxin was given, a degree of immunity sufficient to protect against an attack of scarlet fever was obtained. But, as might be expected, the amount of toxin required to produce immunity, when administered by mouth, was many times the amount which produced comparable immunity when injected subcutaneously.

During the next several years, while experiments were being made to improve the method, immunization by mouth was limited to use in special cases, such as persons in whom hemophilia or severe cardiac lesions had been diagnosed or in institutions under quarantine for scarlet fever when speed in immunization was a prime consideration. It was also occasionally employed in highly susceptible individuals as a preliminary treatment to establish some immunity before hypodermic injections were begun, or in persons so highly sensitized to proteins contained in peptone that hypodermic injections of the toxin resulted in urticaria.

For obvious reasons, commercial distribution of undiluted fluid scarlet fever toxin in 1 liter volumes to be taken by mouth was not practical. It was apparent that it would be desirable to obtain the toxin in a more compact form and, if possible, in a dry state. To obtain such a preparation and to purify as well as concentrate the toxin for further chemical study, investi-

gations were undertaken which have resulted in a highly concentrated and comparatively pure toxin in the form of a white powder.

This substance was carefully standardized, and weighed amounts were combined with pure saccharose to make powders containing different numbers of skin test doses of toxin. Given in these powders, the toxin caused more nausea and vomiting than when it was administered in the liquid state as crude toxin. We concluded that the reason for this difference was that the dry toxin remained in the stomach longer than when it was given in solution.

In an attempt to overcome this difficulty, the toxin was prepared in a saccharose syrup which the children found agreeable but which also caused more nausea than the hypodermic injections, though considerably less than the powders. Probably because of the loss of toxin through vomiting, the powders did not immunize. The syrup, causing less vomiting, produced satisfactory immunity.

In order to eliminate as far as possible nausea with resultant discomfort and sometimes loss of toxin, we decided to try protection of the toxin from absorption in the stomach. Enteric sealed capsules and enteric coated tablets were prepared. Of these two forms the tablets proved easier for small children to swallow. With the cooperation of one of the manufacturers, a number of enteric coated tablets were prepared from the purified toxin. These tablets were made in three strengths: a hundred thousand, one million and two million skin test doses per tablet.

There is considerable variation in the solubility of enteric coated tablets on the market. The solubility depends chiefly on four factors: the kind of substance used for the enteric coating, the thickness of coats applied, the rate of solution of the outer, decorative coat and the motility of the alimentary tract. In persons who have bowel movements at intervals of two or three days the chance of absorption is naturally better than in persons who eliminate residue of food in less than twenty-four hours after ingestion. We have found the standard chemical tests for solubility less satisfactory than actual feeding of the tablets under consideration along with an insoluble tablet, to serve as a marker, to persons known to have a habit of rapid elimination, and searching the stool which contains the marker for other undissolved tablets.

The use of tablets which do not dissolve prevents immunization, while the feeding of tablets that permit release of toxin in the stomach results in vomiting such as occurred when the powdered toxin was introduced directly into the stomach.

Tablets have been employed in the immunization of 131 persons susceptible to scarlet fever. With the exception of one case in this series, the reactions have not been recorded by us but by doctors or nurses in immediate charge of the groups or individuals, and the charts returned when the work was completed. The largest single group comprises fifty-four students at Berea College, where the immunization was supervised by Dr. Armstrong.

Preliminary skin tests were made in every case, and the size and intensity of the reaction were recorded. The skin test was repeated two weeks after completion of the immunization with the exception of one small group which there was no opportunity to retest until two months had elapsed. In the retests, one skin test dose of toxin was injected on the right forearm and two skin test doses on the left forearm. The immuni-

Read in the panel discussion on Some Contagious Diseases before the Section on Pediatrics at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

1. Dick, George F., and Dick, Gladys Henry: Antitoxic Immunity Resulting from Administration of Toxin by Mouth, *J. A. M. A.* 98: 1436 (April 23) 1932.

zation is not considered complete unless the cutaneous reaction to two skin test doses of toxin is negative at the time of retest shortly after completion of the doses.

Preliminary experiments directed toward determining the effective dosage indicated that, while some persons became immune with smaller amounts, the average total dosage should approximate seventy-five million skin test doses of toxin given over a period of three weeks. The tablets were taken immediately after meals, beginning, in most cases, with one hundred thousand skin test doses and gradually increasing to six or ten million skin test doses a day for the last three to six days. No modification of dosage was made on account of age. The series included individuals from 1 to 36 years of age.

In twelve persons the dosage was not carried above one to four million skin test doses a day. All but two in this group showed modified but positive cutaneous reactions on retest.

One group received improperly coated tablets which would partially dissolve in the stomach. In this group, vomiting and diarrhea were frequent complaints. Of the seventeen who completed the course of tablets, eleven, or 64.7 per cent, were immunized. Those who complained of diarrhea, so that they were less apt to absorb the toxin, acquired the least immunity.

Of the 102 persons of various ages who received better toxin tablets in amounts ranging from forty-seven to ninety-one million skin test doses distributed in graduated amounts over a period of two to three weeks, 94.7 per cent were immune on retest. In four cases, or 3.8 per cent, transient scarlatinal rashes occurred at some time, usually on the day four million skin test doses of toxin were given. Two persons vomited once.

With the more gradual increase in dosage in use during the past six months, and stricter control of the solubility of the tablets, reactions have been reduced to an occasional "stomach-ache" of short duration.

The series includes six persons who were so highly sensitized to the proteins contained in peptone that hypodermic injections were considered inadvisable. Their immunization by mouth was successful and uneventful. The further observation was made that, during the course of oral immunization, they became at least partially desensitized to peptone.

Results of further clinical experiments have shown that, whatever type of enteric coating is used, it is necessary to regulate the dosage of scarlet fever toxin according to the rate of disintegration or solution of the tablet. Immunization may be accomplished with doses of toxin smaller than those employed in the first experiments. In instances in which enteric coatings that permitted disintegration of the tablets within three hours in physiologic solution of sodium chloride buffered at p_H 7.0 were employed, the maximum daily dosage required to produce immunity was reduced to one to three million skin test doses of toxin.

It is not suggested that oral administration of toxin be generally substituted at this time for the present method of shallow hypodermic injections of sterile toxin in graduated doses. There are, however, definite advantages in the oral route in the conditions mentioned in the first part of this paper, the additional advantage that it lends itself more readily to modification according to the reactions of the individual patient and that immunization may be accomplished in a shorter time with fewer reactions.

INTRAVENOUS USE OF 2-METHYL-1,4-NAPHTHOQUINONE IN HYPO-PROTHROMBINEMIA

CLINICAL OBSERVATIONS

JOHN W. NORCROSS, M.D.

AND

M. DONALD McFARLAND, M.D.

BOSTON

The isolation and synthesis of vitamin K_1 (2-methyl-3-phytyl-1,4-naphthoquinone) in August of 1939 by Fieser and his associates,¹ by Doisy and his co-workers² and by Almquist and Klose³ gave new impetus to the clinical evaluation of the antihemorrhagic activity of synthetic vitamin K_1 and its chemical derivatives in hypoprothrombinemia. It has been amply established by Ansbacher and his associates⁴ and by others⁵ that 2-methyl-1,4-naphthoquinone and more recently that 2-methyl-1,4-naphthohydroquinone are more rapidly acting and have greater potency than the many other derivatives of vitamin K_1 thus far elaborated in the biochemist's laboratory.

It is our purpose in this paper to report our experience with the intravenous use of 2-methyl-1,4-naphthoquinone for patients suffering from hypoprothrombinemia.

CHEMISTRY

Numerous chemical compounds closely related to the naturally occurring vitamin K_1 of alfalfa and K_2 of putrefied fish meal have been made available for clinical research, and certain facts have been established. Those compounds containing the phytyl group are less rapidly utilized by the animal's body.⁶ The hydroxy group in the 3 position appears to reduce potency,⁷ while the methyl group in the 2 position has been found essential. 2-methyl-1,4-naphthoquinone is a canary yellow crystalline substance, readily soluble in oil and slightly soluble in warm water (1 mg. in 10 cc.). The solution slowly loses potency on exposure to light but retains its activity in a dark refrigerator for several days. We have used 2-methyl-1,4-naphthoquinone exclusively in this study.

TOXICITY

Molitor and Robinson⁸ determined the acute and chronic toxicities of 2-methyl-1,4-naphthoquinone on mice, rats and chicks. They found a very large safety

factor between the toxic and therapeutic doses; 500 mg. per kilogram of body weight was the L. D. 50 orally in mice with this substance. Chronic toxicity in rats was tested over a period of thirty consecutive days on varying daily doses; 500 mg. per kilogram of 2-methyl-1,4-naphthoquinone was toxic and 350 mg. per kilogram caused a marked fall in red blood cell count and

Prothrombin determinations were made immediately before intravenous treatment was administered and at varying intervals thereafter. We have considered a prothrombin clotting time of 90 per cent or over as normal.

The solution of crystalline 2-methyl-1,4-naphthoquinone¹¹ was prepared by dissolving 10 mg. in 100 cc. of sterile hot physiologic solution of sodium chloride. This was used immediately or was protected from light and stored for short periods of time in the refrigerator. The intravenous injection was made slowly into an ante-cubital vein.

RESULTS

During the seven months between February and September of 1940 we have administered 2-methyl-1,4-naphthoquinone intravenously to twenty-two patients, twenty of whom had hypoprothrombinemia. A brief outline of these cases, together with their response to treatment is presented in table 1. The conditions considered most important in causing the hypoprothrombinemia in each case have been summarized in table 2. Patients 8 and 16 received 2-methyl-1,4-naphthoquinone prophylactically. The response to intravenous treatment was considered good in 17 (77.3 per cent), fair in 2 (9.1 per cent) and poor in 3 (13.6 per cent).

In attempting to establish the minimum effective intravenous dose of 2-methyl-1,4-naphthoquinone in the adult it was demonstrated that although 1 mg. would usually cause a definite rise in the prothrombin level a second milligram dose was needed before a normal prothrombin could be obtained. Patient 4 showed a complete response to 1 mg. intravenously, but this

Chart 1.—Effect of 1 mg. intravenous doses of 2-methyl-1,4-naphthoquinone on hypoprothrombinemia.

in hemoglobin. Natural vitamin K₁ did not cause these changes.

In the human being no toxic effect from 2-methyl-1,4-naphthoquinone has been reported when small oral doses were used, but Koller⁹ has described nausea and vomiting following the oral administration of large doses (3 mg. per kilogram of body weight).

METHOD

In this study we have used Quick's¹⁰ method of prothrombin time determination but have reported this

in terms of percentage of normal as suggested by H. J. Perkin of the clinic's research laboratory early in our investigation of vitamin K and related prothrombogenic substances. This method permits minor changes in potency of the thromboplastic substance without affecting the final result in the individual test. The patient's prothrombin time in percentage of normal is calculated by dividing the patient's prothrombin clotting time by the normal control's prothrombin clotting time and multiplying by 100.

patient was a 3 year old child. Chart 1 demonstrates the limitation of response to the 1 mg. dose in the adult.

The effect of a 2 mg. dose of 2-methyl-1,4-naphthoquinone intravenously is shown in chart 2. These patients were selected to demonstrate this point because of their initial low levels of prothrombin and because liver damage, with the exception of case 17, was absent or of such degree as not to interfere seriously with the

11. The crystals were supplied to us by E. R. Squibb & Sons.

response. From these results we conclude that some patients may be expected to show beginning effect as early as two hours after receiving intravenous medication, that a prothrombin level of 80 per cent of normal is reached in an average of about seven and one-half hours, and that 100 per cent of normal is attained in an average of about twenty hours.

The duration of the effect of 2 mg. of 2-methyl-1,4-naphthoquinone is shown in chart 3. It is seen that the prothrombin level will remain above 90 per cent of normal for four or more days unless complicated by liver damage. Case 17, in which there was some liver impairment, also appears on the chart and shows a more rapid drop.

We have confirmed the reports of numerous other investigators with regard to the effect of liver damage and have found no increased response in such cases by the intravenous route of administration as compared with the oral route. The patients who responded slowly or incompletely suffered, without exception, from

Chart 3.—Duration of effect after 2 mg. intravenous dose of 2-methyl-1,4-naphthoquinone on hypoprothrombinemia.

some degree of liver damage. This was demonstrated in some cases by liver function tests and in others by direct observation of the liver at operation. Severe liver damage was necessary to prevent more than a slight response to intravenous 2-methyl-1,4-naphthoquinone (cases 1 and 7). When the impairment of liver damage was less severe, some initial increase in prothrombin occurred but the response was not complete and the prothrombin clotting time could not be lowered to a completely normal level nor could it be maintained as easily as in those cases in which there was no appreciable liver damage (cases 5, 10, 13, 15, 17 and 21). Repeated intravenous doses in this group sometimes led to more normal levels (case 15).

In nine cases bleeding occurred before the administration of 2-methyl-1,4-naphthoquinone, but bleeding was effectively controlled except in cases 1 and 5, in which severe liver damage existed.

By this route of administration bile salts were not necessary.

Except for the temporary pain near the site of injection in five cases, no toxic effects were noted. In no case could any drop in blood count or hemoglobin level be attributed to this drug.

REPORT OF CASES

We have chosen four illustrative cases to present in detail:

CASE 1.—A man aged 43, a druggist, entered on Jan. 23, 1940, with a story of recurrent jaundice of two years' duration. He had been a heavy drinker for three years before the onset of this condition but had consumed no alcohol in the two years previous to entry. There had been no pain, chills or fever. Roentgenograms taken elsewhere two weeks before entry were said to show a stone in the gallbladder region. Slight epistaxis had occurred occasionally, as well as some bleeding from the gums.

Physical examination showed the scleras to be slightly icteric. The skin was dry and there were a few follicular keratoses on the arms. On the lower legs were several papular, purpuric, pin point lesions. The liver extended from the sixth interspace superiorly to a sharp edge 3 fingerbreadths below the right costal margin. It extended well into the epigastrium and was smooth, firm and slightly tender. The splenic tip descended 2 fingerbreadths below the left costal margin. No ascites could be elicited. There were numerous dilated venules over the lower anterior chest wall bilaterally. There was no peripheral edema.

The patient was sent immediately into the hospital with the diagnosis of biliary cirrhosis and a question of cholelithiasis. Laboratory test showed 15.6 Gm. of hemoglobin (100 per cent Sahli), 5,000,000 erythrocytes and 6,330 leukocytes. The prothrombin time was 65 per cent; the bilirubin showed an indirect reaction and was 2.8 mg. per hundred cubic centimeters. The urobilinogen was positive in 1:256 dilution. The serum protein was 7.5 per cent, the Hinton test was negative and the urine was normal. The icteric index was 45. The Takata-Ara test was strongly positive and 80 per cent of the bromsulphalein was retained after one hour.

The patient was given vitamin B complex by mouth and members of the B complex intramuscularly. He was given 2-methyl-1,4-naphthoquinone orally in 2 mg. doses three times a day, together with bile salts 10 grains (0.65 Gm.) three times a day. At the end of nine days the prothrombin had risen to 75 per cent and at this time natural vitamin K₁ was given orally with bile salts, without any further rise in the prothrombin time.

In spite of the evidence of hepatitis and our inability to raise the prothrombin time to a normal level, an exploration was deemed necessary. This was done February 10. A markedly scarred liver was found, but no stones were felt. The liver biopsy showed a toxic hepatitis with cirrhotic changes.

The patient did poorly after operation. His prothrombin dropped to 53 per cent of normal, and oral 2-methyl-1,4-naphthoquinone, together with bile salts, raised this to 67 per cent of normal.

On the seventh postoperative day the patient began to show evidence of cholemia and uremia and vomited a total of about 6 ounces (178 cc.) of blood. His prothrombin time was 67 per cent of normal, and 2 mg. of 2-methyl-1,4-naphthoquinone was given intravenously. The poor prothrombin response is shown in table 3.

The patient died on the eighth postoperative day. Postmortem examination showed toxic cirrhosis of the liver with a superimposed subacute yellow atrophy, massive gastrointestinal hemorrhage and cholelithiasis with soft stones in the bladder but none in any of the ducts.

CASE 4.—A boy aged 3 years was brought to the clinic on Jan. 31, 1940, because of an abdominal mass present since the age of 12 months and jaundice of two weeks' duration. The parents had been told that the abdominal mass was an enlarged liver. There had been several attacks of cough, anorexia, clay-colored stools, dark urine and general malaise. During these attacks the abdominal mass increased in size, but as the symptoms subsided the mass became smaller and the color of the

stools and urine returned to normal. Jaundice had been present for about two weeks before admission and there had been a mild pruritus for several days.

On physical examination the boy was well developed and well nourished, with moderate pallor of the mucous membranes and a mild icterus of the scleras. There were a few excoriations on the skin of the trunk and legs. A few medium rales were heard throughout both lung fields. Examination of the abdomen

revealed a cystic mass approximately 9 cm. in diameter in the right half of the abdomen. The spleen was not palpated. A few shotty cervical glands were felt. The temperature was 99 F. by rectum, the weight 35½ pounds (16 Kg.) and the height 39½ inches (100 cm.). The rest of the physical examination gave essentially normal results.

The urine on admission showed a trace of bile but was otherwise negative. The bile gradually increased in the urine after entry, the leukocyte count was 11,450, hemoglobin 62 per cent (Sahli), erythrocytes 4,080,000, differential 80 per cent polymorphonuclears, 17 per cent lymphocytes, 3 per cent monocytes. The icteric index was 17 and the hematocrit reading 40. The bilirubin was 1.4 mg. per hundred cubic centimeters. The platelet count was 544,000, the reticulocyte count 1.9 per cent. There was moderate achromia. The stools showed a trace of bile.

After a mild bronchitis had cleared, exploratory operation was performed on February 15. At this time a congenital dilatation of the common bile duct, containing about a liter of bile, was found, and marsupialization of the dilated duct was carried out. The prothrombin clotting time preoperatively was 100 per cent of normal and remained so immediately after operation. Large amounts of bile drained through the catheter which had been placed in the common bile duct and an attempt was made to give the patient bile salts by mouth. This was only partially successful, as he refused this medication on and after March 13. On March 18 the urine began to show many red blood cells in the sediment. On March 21 he became nauseated and vomited several times, was listless and had a fever of 101 F. by rectum in the evening. A hypodermoclysis was given on this date and there was some bleeding from the

skin wounds after the withdrawal of the needles. The next day, March 22, he bled from the needle wound in the lobe of the ear where blood had been taken. On March 23 bright red blood was passed by rectum and the bleeding continued from the ear lobe and from the nose.

Examination of the blood at this time showed a leukocyte count of 16,000, and the hemoglobin had dropped from 89 per cent on March 1 to 60 per cent. The prothrombin clotting time on March 23 was found to be 10 per cent of normal. At 5 p. m. 1 mg. of 2-methyl-1,4-naphthoquinone, dissolved in 10 cc. of physiologic solution of sodium chloride was given intravenously. By 7 o'clock the same evening all bleeding had stopped, and

eighteen hours after the medication the prothrombin time was 100 per cent of normal.

The patient's clinical condition improved markedly, his temperature fell to normal, his appetite returned and he was again running about the wards. He was then given tiny repeated doses of bile salts and 6 mg. of 2-methyl-1,4-naphthoquinone orally each day. The prothrombin time remained 100 per cent of normal. On March 30, choledochoduodenostomy was performed. The patient was discharged on April 13, with normal colored stools and urine, and with all evidence of jaundice gone.

CASE 9.—A man aged 42, a druggist, admitted on May 17, 1940, had had attacks of epigastric pain during the previous year extending to the right scapular region. Three weeks before entry he had undergone a cholecystectomy elsewhere, at which time several stones were removed. Following this procedure he had become intensely jaundiced, had experienced chills and fever, and had noted dark urine and light colored stools. One week before entry a biliary fistula had developed and the jaundice had partially subsided.

Physical examination was essentially negative except for moderate icterus of the skin and scleras, a palpable liver edge 1 fingerbreadth below the right costal margin and a biliary fistula.

The patient entered the hospital on the same day. The icteric index was 35, the hemoglobin 91 per cent (Sahli), the erythrocytes 5,010,000 and the leukocytes 5,500. The serum bilirubin was 7.8 mg. per hundred cubic centimeters (indirect). May 18

TABLE 5.—Response to 2-Methyl-1,4-Naphthoquinone in Case 10

Date	Prothrombin Time, per Cent	2-methyl-1,4- naphthoquinone

at 9 p. m. the prothrombin time was 49 per cent of normal and at this time 2 mg. of 2-methyl-1,4-naphthoquinone was given intravenously. His prothrombin response is shown in table 4.

On May 21 operation was performed and a transfusion of 500 cc. of citrated blood given. The common duct was found to have been divided and the intrahepatic portion of the common duct was anastomosed to the jejunum. The postoperative course was uneventful. The prothrombin time gradually fell to 71 per cent of normal on May 27, and at this time natural vitamin K₁ and bile salts were started by mouth. On June 6 the prothrombin time had risen to 89 per cent. The patient was discharged markedly improved on June 9, at which time his icteric index was 9 and the bilirubin 0.1 mg. per hundred cubic centimeters (indirect).

CASE 10.—A woman aged 31, a housewife, entered the clinic on May 18, 1940, complaining of the presence of a bile fistula of five months' duration. She had had a cholecystectomy elsewhere in 1931 and in November of 1939 had had a recurrence of right upper quadrant pain. In January 1940 another operation was performed elsewhere and she was told that her common bile duct had "shriveled up." A T tube had been sutured in place and was there on admission to the hospital. At this time there was slight bleeding around the tube.

On physical examination the patient appeared thin and jaundiced and was in no acute distress; she showed general malnutrition and tenderness in the right upper quadrant, where there was a rubber catheter in place.

She entered the hospital immediately and there a urine examination revealed albumin 3+ and bile 2+. The bilirubin was 9.0 mg. per hundred cubic centimeters, the nonprotein nitrogen 21 mg. per hundred cubic centimeters. The leukocytes numbered 11,750, the erythrocytes 3,440,000; the hemoglobin was 66 per cent (Sahli). The differential was normal. The Hinton test was negative. Examination of the stools showed

a 3+ benzidine test for blood and no bile. The prothrombin time was found to be 50 per cent of normal.

The patient was given 2 mg. of 2-methyl-1,4-naphthoquinone intravenously, and the response is shown in table 5.

On May 22 the patient underwent operation, and a stricture at the ampulla of Vater was found. This was dilated and a T tube left in the common bile duct. Four days after operation the prothrombin had fallen to 83 per cent. At this time she was given a transfusion of 250 cc. of citrated blood and on the seventh postoperative day the prothrombin time had dropped to 55 per cent and she started to bleed. At this time she was given another 2 mg. of 2-methyl-1,4-naphthoquinone intravenously, and the prothrombin time was brought up to 83 per cent of normal in two days. All bleeding had stopped five hours after the medication had been given intravenously. At this time she was given natural vitamin K₁ and bile salts by mouth three times a day, and the prothrombin time rose to 100 per cent. On June 19 the T tube was removed. Following this a temperature of 102.4 F. developed and the bilirubin rose to 17.0 mg. per hundred cubic centimeters. On June 21 the prothrombin had dropped to 65 per cent and she again received 2 mg. of 2-methyl-1,4-naphthoquinone intravenously, but the prothrombin time remained low in spite of the fact that the dose of 2 mg. was repeated in twenty-four hours and 1 mg. in forty-eight hours. At this time an intravenous hippuric acid test was less than 0.44 Gm., thus showing marked liver damage, which was thought due to hepatitis.

The fever gradually subsided and the bilirubin dropped to 13 mg. per hundred cubic centimeters. The patient was given 2-methyl-1,4-naphthoquinone and bile acids by mouth. As the evidence of hepatitis subsided the prothrombin gradually rose to 90 per cent in the course of the next four days. She was discharged improved on June 28.

Case 1 demonstrates the ineffectiveness of 2-methyl-1,4-naphthoquinone when severe liver damage existed. Case 4 illustrates the dramatic effect of this drug in bleeding due to hypoprothrombinemia. In case 9 the average response of uncomplicated vitamin K deficiency to 2-methyl-1,4-naphthoquinone, given intravenously, is shown. Case 10 contrasts the effect of 2-methyl-1,4-naphthoquinone in hypoprothrombinemia before, during and after the development of liver impairment.

COMMENT

The value of the prothrombogenic chemicals in raising lowered blood prothrombin levels has been amply demonstrated. 2-methyl-1,4-naphthoquinone by the intravenous method of administration has proved highly effective. The minimum effective dose has been found to be 2 mg. for the adult. Although this dose has had a definite effect within two hours and has raised low levels to an entirely normal figure in twenty hours, it may well be that larger doses would result in earlier normal values and that the duration of effect might be substantially prolonged. Further investigation along these lines is to be desired. The possible prolongation of effect with greater doses depends largely on the ability of the body and especially of the liver to store prothrombin or its precursor, a point needing clarification.

Although severe liver damage appears necessary to prevent adequate elevation of the blood prothrombin after the intravenous injection of 2-methyl-1,4-naphthoquinone, lesser degrees of liver impairment appear to lead to a slower onset of response, a lessened height of response and a response of shorter duration. Under certain circumstances the application of these facts may be of definite value in determining the degree of impairment of one important liver function. We feel that transfusions should be delayed when possible until after the patient's response to the prothrombogenic substance has been determined in order that poor liver function

may not be obscured. Patients who have been unable to raise their prothrombin to a normal level when 2-methyl-1,4-naphthoquinone has been given intravenously before operation have done poorly after operation.

While the intravenous mode of administration presents definite advantages under circumstances in which oral administration is not feasible, as in nauseated patients or when the most rapid effect is essential as in bleeding, we do not propose that this route be used in all cases, the oral method being considered simpler for the average patient. The instability of the aqueous solution of 2-methyl-1,4-naphthoquinone and the ease with which this chemical is precipitated from solution when chilled are disadvantages to its routine use.

As previously stated, we have considered any prothrombin figure 90 per cent or above as normal. We wish to stress the importance of attaining an entirely normal figure before surgery is attempted, since it is wise to know that a normal level can be reached or that liver damage prevents this response. Much prothrombin may be lost during operation because of blood loss, and this may cause the already lowered prothrombin to fall to a dangerous level. We have found that in some cases bleeding may occur with a prothrombin level as high as 70 per cent of normal, although this is true usually for patients with considerable liver damage and confirms the probability that other factors are involved in this bleeding.

SUMMARY

1. 2-methyl-1,4-naphthoquinone has been administered intravenously to twenty-two patients. It has proved to be efficient in raising the prothrombin level. Bile salts were not necessary for this response.
2. With the exception of local distress of short duration at the time of injection, no toxic manifestations have been observed.
3. The minimal effective intravenous dose of 2-methyl-1,4-naphthoquinone in the adult was found to be 2 mg.
4. In cases uncomplicated by liver impairment a 2 mg. dose given intravenously raised the prothrombin level from 50 per cent to 80 per cent in an average of seven and one-half hours and to 100 per cent in an average of twenty hours.
5. A 2 mg. intravenous dose kept the prothrombin level above 90 per cent of normal for four or more days unless liver damage was present.
6. Severe liver damage permitted only a slight response to intravenous 2-methyl-1,4-naphthoquinone. If liver impairment was less marked, the effect was manifested in a slower onset of response, a lessened height of response, and a shorter duration of response.
7. Bleeding was rapidly and effectively controlled unless severe liver damage was present.
8. The intravenous route of administration has great value in patients for whom oral administration is difficult or impossible, as well as in those cases in which rapid cessation of bleeding is imperative.

A Pilot May Faint.—Human physiology sets no definite speed limit, but, if you are going fast, turning is dangerous, because it drains the blood into the parts of the body on the outside of the turn and may cause fainting. In particular, if a pilot turns a rapidly moving aeroplane upwards, his blood is forced down into his legs, and he may faint.—Haldane, J. B. S.: *Science and Everyday Life*, New York, Macmillan Company, 1940.

ORTHOSTATIC HYPOTENSION AND
ORTHOSTATIC TACHYCARDIA

TREATMENT WITH THE "HEAD-UP" BED

ALEXANDER R. MacLEAN, M.D.

AND

EDGAR V. ALLEN, M.D.

ROCHESTER, MINN.

Orthostatic hypotension is characterized chiefly by a sharp decrease in blood pressure when a patient afflicted with it stands. The blood pressure is ordinarily normal when the patient lies. If the blood pressure decreases to a low level, weakness and syncope result. Other relevant signs or symptoms are deficient sweating, either localized or generalized, secretion of larger amounts of urine when the patient is recumbent than when he is erect and in some cases a failure of the pulse rate to increase markedly when the patient assumes the erect posture. Orthostatic hypotension should be suspected whenever a patient has exhaustion in the morning which lessens during the day, whenever weakness, dimness of vision or syncope occurs on assumption of the erect posture and disappears on lying down, whenever episodes of syncope are inadequately explained and whenever there is diminished sweating. This condition has been considered by some to be the result of failure of adequate constriction of arterioles when patients stand.¹ The failure of the arterioles in turn has been assumed to result from a defect in the autonomic nervous system. This concept has been based on logical interpretations of clinical data: 1. Extensive sympathectomy in cases of essential hypertension results in a diminution of arteriolar tone which has seemed to explain the orthostatic hypotension which ordinarily results from extensive sympathectomy. 2. Drugs which increase arteriolar tone dramatically relieve the orthostatic symptoms and markedly improve the blood pressure in the erect posture.² The natural assumption followed that it is deficiency in arteriolar resistance which results in the low blood pressure when the patient stands. 3. The disturbances in sweating frequently found in cases of orthostatic hypotension have appeared to demonstrate a primary disturbance in the autonomic nervous system.¹ Hypofunction of this cholinergic part of the autonomic nervous system seemed an index of a similar disturbance in the adrenergic portion of the autonomic nervous system which resulted in a loss of arteriolar tone.

Recent studies, which we are not presenting in detail in this paper, suggest that the defect in postural adaptation is not a defect in arteriolar vasoconstriction but rather one in the maintenance of adequate return of venous blood to the heart. The evidence in brief may be summarized as follows: 1. Weiss and his associates have shown that circulatory collapse may be induced by the erect posture when normal subjects

are given appropriate amounts of sodium nitrite.³ Syncope produced by this artificial method appears to be the result of the loss of venous tone and the pooling of blood in the dependent portions of the body and closely resembles the syncope observed in cases of orthostatic hypotension. 2. We have been able to demonstrate a deficient "potential" in the venous return to the heart in all cases of orthostatic hypotension which we have studied by the Flack test, which consists in having the patient blow against the column of mercury of a sphygmomanometer with the glottis open.⁴ The resulting increase in intrathoracic pressure increases the resistance which the venous blood has to overcome in traveling back to the right side of the heart and is a measurement of the potential of the venous return. Normal subjects can maintain the mercury column at 40 mm. of mercury for periods of at least twenty-five seconds, with little change in pulse rate or blood pressure. Patients with orthostatic hypotension become pulseless and collapse within a period of ten seconds. Fluoroscopic and roentgenographic studies of the heart show a diminution in the size of the heart and great vessels during this period of increased intrathoracic pressure (fig. 1). However, when these patients are placed in a recumbent position with the head 30 degrees lower than the feet, the Flack test approaches normal in some cases. 3. The temperature of the skin of the toes and of the fingers of two individuals with orthostatic hypotension changed in a normal fashion in response to different environmental temperatures and to application of heat to the trunk. These studies indicate that the peripheral arterioles respond normally by dilatation and constriction in a reflex manner to changes in temperature. The autonomic innervation of the arterioles seemed, therefore, to be intact functionally.⁵ 4. In cases of orthostatic hypotension the peripheral arterioles offer adequate resistance to maintain the blood pressure at normal levels when the patient is recumbent. It seems illogical that simple assumption of the erect posture could cause loss of arteriolar tone. 5. The arteriolar vasoconstricting substances ephedrine, epinephrine, paredrinol (racemic parahydroxy- α ,N-dimethylphenethylamine) and amphetamine raise the whole level of blood pressure in cases of orthostatic hypotension, but use of them does not prevent the abnormal decrease in blood pressure when patients stand.

These five observations suggest that there is no deficiency in arteriolar tone in the syndrome of orthostatic hypotension but rather that there is a diminution in the maintenance of adequate return of venous blood to the heart, which results in a diminished cardiac output and a decrease in the arterial blood pressure when patients stand.

ORTHOSTATIC HYPOTENSION

An attempt to find a remedy for orthostatic hypotension in the field of vasoconstricting drugs has proved in our hands disappointing. We have used ephedrine,

From the Section on Neurology (Dr. MacLean) and the Division of Medicine (Dr. Allen), the Mayo Clinic.

paredrine (parahydroxyphenylisopropylamine), prostigmine methylsulfate and guanidine hydrochloride. These substances have given symptomatic relief and they have prevented the reduction of blood pressure to a low level when patients stand. However, in two cases which we studied carefully the beneficial results were only temporary.

During investigation of the value of various therapeutic procedures, we noted that patients with orthostatic hypotension appeared to improve symptomatically and objectively during the daytime and that this improvement had disappeared in the morning after sleep in bed at night. The implication in this observation was that these patients lost some of their ability to adapt themselves to changes in posture as the result of either sleep itself or as a result of the recumbent position in which they slept. This observation led to the suggestion that patients with orthostatic hypotension should not sleep in a flat bed but should lie in a semi-inclined or "head-up" position⁶ (fig. 2). The results of this type of treatment have been so startling

resulted in improvement in the subjective symptoms. When the patient stood his blood pressure was higher than before the drug was given. Guanidine hydrochloride given orally was even more beneficial and on this medication he remained free from symptoms for a week. At the end of this time both prostigmine and guanidine appeared to lose their effect, and the patient reverted to his former condition. Medication with ephedrine and amphetamine was only temporarily beneficial. The patient's condition became steadily worse and for a period of three months prior to his last examination he was confined to bed and to a wheel chair.

The patient returned to the clinic March 25, 1940. The orthostatic hypotension had greatly increased. Several determinations of blood pressure with the patient recumbent averaged 130/80. The patient was unable to stand erect for longer than three minutes because of syncope which then occurred. The blood pressure at the end of one minute of standing in the erect posture could not be obtained. The patient was unable to sweat over the face, trunk and extremities when his body was subjected to radiant heat. Paredrinol, prostigmine methylsulfate, epinephrine and guanidine hydrochloride did not significantly change the blood pressure when the patient was erect or alleviate the patient's disability (fig. 3).

Fig. 1.—Evidence of the effect of increased intrathoracic pressure on size of the heart and great vessels: (a) control; normal inspiration; (b) Flack test of 40 mm. of mercury at the end of five seconds; (c) expiration at the completion of the Flack test.

that we are reporting illustrative cases. The following is a case of spontaneous orthostatic hypotension:

A man aged 59 first registered at the Mayo Clinic July 5, 1939. He complained of dizziness, blurring of vision, exhaustion and syncope associated with standing erect. These symptoms had begun insidiously a year prior to registration and had progressed to the point of severe disability. He was unable to walk more than two blocks without resting. He presented the typical features of spontaneous orthostatic hypotension. The recumbent blood pressure in millimeters of mercury was 130 systolic and 80 diastolic; at the end of one minute of standing it was 70/40. At the end of five minutes of standing the blood pressure was 55/45. The heart rate did not increase when the patient stood. The Flack test gave positive results. When the patient blew the mercury column to the 40 mm. mark, syncope resulted at the end of five seconds. When the patient was in the recumbent position and was tilted with the head down at an angle of 30 degrees, he was able to blow the mercury column to the 50 mm. mark and retain it there for a period of twenty-two seconds without syncope. Roentgenoscopic and roentgenologic studies of the heart during the periods of increased intrathoracic pressure showed diminution in the size of the heart and in the size of the great vessels in the mediastinum when the patient blew against a column of mercury. The administration of prostigmine methylsulfate subcutaneously

The patient was then placed in a bed the head of which was elevated 18 inches. During the daytime he was encouraged to sit in a chair. Improvement occurred quickly. The patient was able to stand erect for longer and longer periods. He became more active and was capable of walking for short distances. At the end of four days of this treatment the patient was able to stand erect for periods longer than an hour without syncope. When he stood the blood pressure slowly fell from 100/60 to 60/40 at the end of an hour (fig. 4). Previously the best effect of treatment was ability to stand ten minutes following the injection of epinephrine (fig. 3). The improvement could be made to disappear, for when the patient slept one night in a level bed the blood pressure on the following morning when he was in the erect posture could not be obtained and syncope occurred within one minute.

The patient has continued to sleep on the tilted bed since that time. Within two weeks he went to work for the first time in seven months. Two months after treatment on the tilted bed had been begun he had not had an attack of syncope. At present he works six hours a day in his office and two hours a day in his garden. He has recovered his ability to sweat over his face, arms and trunk. He is not, however, cured of vascular disability, for he still has orthostatic hypotension. In the erect posture the blood pressure still decreases to 60/40 at the end of an hour, but he has recovered a measure of postural vascular adaptability sufficient to allow him to function in a comparatively normal fashion. We do not pretend that the tilted "head-up" bed alone has been responsible for this improvement. It has been instrumental in preventing the loss of postural

⁶ Paper to designate a bed with the head of the head of a bed on 18 inches. Patients sleep comfortably in this position, although some may need a hard pillow under the mattress at the level of the thighs to prevent slipping.

vascular adaptability which the patient gained during the day-time and which previously he had been losing by sleeping on a flat bed.

The following case is one of orthostatic hypotension induced by sympathectomy for essential hypertension:

A woman aged 34 had an extensive sympathectomy performed May 28, 1940, because of essential hypertension. June 6 a similar operation was performed on the left side. June 24 the blood pressure decreased from 160/110 when she lay to 60/40 after standing for forty-five seconds, at which time she became so weak that she was forced to lie again to prevent syncope. The pulse rate increased from 94 per minute on lying to 140 when she stood. For three days she slept on the "head-up" bed at night and sat in a chair or walked a little during the day. At the end of this period she could stand or walk without weakness or syncope. She felt entirely well and she was able to stand for thirty minutes without symptoms. The blood pressure when lying was 130/100 and her pulse rate 70 per minute. The blood pressure when she stood was 150/100 and the pulse rate was 100. For the next twenty-four hours the patient slept on a horizontal bed at night and continued as active as her strength permitted during the day. The blood pressure while lying in bed then was 144/110 and the pulse rate 78. She could stand for only forty-five seconds because of weakness. The systolic blood pressure at the end of this time was 50 mm. of mercury and the diastolic blood pressure could not be determined. The pulse rate was 130 per minute. During the next

Fig. 2.—The tilted "head-up" bed.

day she rested or slept on the "head-up" bed or rested in a chair. At the end of this period when she lay in bed the patient's blood pressure was 148/112 and her pulse rate was 90. At the end of five minutes of standing the blood pressure was 96/70 and the pulse rate 138. She felt better than she had on the day before but did not feel entirely well. The patient continued to sleep or rest on the "head-up" bed for two days and her condition continued to improve. At the end of this time, the respective values for blood pressure and pulse when she lay were 140/112 and 72. After five minutes of standing they were 146/110 and 124. She felt entirely well. During a subsequent period of twenty-four hours she slept or rested on a horizontal bed. At the end of this time she was unable to stand for a minute because of syncope. The blood pressure was indiscernible and the pulse rate increased to 150 per minute just before she fainted.

Study of the patient demonstrated unequivocally that resting and sleeping on the "head-up" bed prevented orthostatic hypotension and the symptoms associated with it.

ORTHOSTATIC TACHYCARDIA

We have given the name orthostatic tachycardia to a syndrome which is characterized by an excessive acceleration of the heart when the patients change from the recumbent to the erect posture. Orthostatic exhaustion, blurring of vision, weakness on exercise and syncopal episodes may occur. There is usually no

orthostatic hypotension present. Sweating is normal. This is a syndrome which seems identical with or similar to those characterized as effort syndrome, irritable heart or neurocirculatory asthenia. The symptoms and objective signs are immediately relieved when the patients lie down and as with orthostatic hypotension these patients exhibit an exacerbation of symptoms in the morning following a night of rest on a flat bed.

Fig. 3.—Blood pressure determinations in the erect posture following 0.75 Gm. of guanidine hydrochloride administered orally, 40 mg. of paredrinol sulfate administered intramuscularly and 1 mg. of epinephrine administered subcutaneously. In each instance the upper line indicates the systolic blood pressure and the lower line indicates the diastolic blood pressure. They are designated S and D respectively in that part of the chart showing the effect of guanidine. During the control period the patient fell in syncope at the end of one minute. At the height of the reactions to guanidine and paredrinol the patient fell at the end of five minutes. At the height of the reaction to epinephrine the patient fell at the end of ten minutes.

Symptoms and objective signs improve during the course of the day.

In our experience the Flack test has demonstrated an inherent defect in the mechanism for returning venous blood to the heart similar to that demonstrated in cases of orthostatic hypotension and it is our impression that the underlying pathogenesis is a diminution of "potential" of return of venous blood to the heart

Fig. 4.—Blood pressure determinations in the erect posture after four nights of treatment with the tilted "head-up" bed. The patient was capable of standing for an hour without syncope.

rather than defective arterioles. It would appear that if these patients did not have orthostatic tachycardia they might have orthostatic hypotension. Following is an illustrative case of orthostatic tachycardia:

A physician aged 30 registered at the Mayo Clinic May 15, 1940. He complained of exhaustion and attacks of unconsciousness. Symptoms had begun a year and a half previous to registration, when he was working for long hours in a hospital spending many nights sitting up with his father, who was very

ill. At that time his wife noticed episodes characterized by unsteadiness in standing and walking, slowness and uncertainty of speech and pallor and exhaustion. His condition became progressively worse. The patient omitted breakfast once in September 1939 and an hour after arising fell and was unconscious for a minute. Hypoglycemia was suspected but studies of sugar in the blood did not confirm this suspicion. The exhaustion, weakness and difficulty in talking and walking became more pronounced, forcing the patient to terminate his hospital appointment and to go into general practice. In May 1940 he experienced two more episodes of unconsciousness of short duration.

A general physical examination demonstrated no abnormalities of note. A repetition of the dextrose tolerance studies and a thirty hour fast appeared to exclude hypoglycemia as a cause for the patient's ill health. Neurologic and electro-encephalographic examinations gave essentially negative results. The patient, however, had marked orthostatic tachycardia. In the recumbent position the blood pressure was 155/90, with a heart rate of 80 per minute. When in the erect posture the blood pressure varied between 120/80 and 100/70 and the heart rate averaged 150 beats per minute. The Flack test demonstrated a marked deficiency in the potential of venous return. When the patient blew the mercury column to the 40 mm. mark, the pulse disappeared at the end of ten seconds and the patient experienced a marked feeling of weakness and syncope.

In view of the obvious orthostatic vascular defects, the patient was questioned in detail concerning the time his symptoms occurred and it was discovered that the exhaustion, weakness and syncope episodes had all occurred during the morning hours shortly after arising from a night of rest in bed. The patient and his wife had noticed that he improved as the day progressed unless he was subjected to some unusual strain.

The patient was placed on a tilted "head-up" bed, the head of which was raised 18 inches. On the following morning a distinct improvement occurred subjectively and this improvement was reflected in the heart rate with the patient standing. Following the second night on the tilted bed the patient's blood pressure in the erect position was 130/90, with a pulse rate of 80 beats per minute. This improvement continued as long as the patient was kept on the tilted bed at night. When he was again placed on a flat bed he reverted overnight to his previous condition, associated with a heart rate of 140 beats per minute when standing.

The patient returned home on a regimen of increased physical exercise and of sleeping on a tilted bed at night. His pulse rates in the erect posture and after mild exercise consistently remained less than 100 beats per minute. He experienced a return to normal health. One month after returning home, the patient was asked to sleep on a flat bed and within forty-eight hours his symptoms of exhaustion and weakness had returned and he experienced a severe syncope episode with loss of consciousness. He promptly returned to the use of a tilted bed and all symptoms completely disappeared within twenty-four hours. He has written: "My work has been very heavy during the past weeks but I have been able to do it with far greater ease than ever before. After returning to the tilted bed there have been no periods of weakness or any other symptoms."

The following case is illustrative of a combination of orthostatic hypotension and tachycardia associated with the clinical picture of subacute combined sclerosis:

A woman aged 47, who registered at the Mayo Clinic June 10, 1940, complained of numbness and tingling of the finger tips, weakness and staggering gait of six months' duration. She had had anemia for twenty years and recurring attacks of glossitis for ten years. Achlorhydria was known to have been present for eight years. She had been treated with iron but not with liver.

The average number of erythrocytes was 3,300,000 per cubic millimeter of blood. The concentration of hemoglobin was 8.5 Gm. in each 100 cc. of blood and the color index was less than 1. Hypochromic anemia was apparent on microscopic examination. The majority of the erythrocytes were microcytes but there was an occasional macrocyte. There was no shift of the polymorphonuclear leukocytes to the right. Free hydrochloric acid was absent in the gastric contents, even after stimulation with

histamine. Neurologic examination demonstrated the typical symptoms and signs of subacute combined sclerosis consisting of marked diminution of the deep reflexes of the lower extremities, bilateral Babinski phenomena, ataxic gait and absent vibration sense over the lower extremities and iliac crests. Joint sense of the legs was markedly impaired and Romberg's sign was present. During the process of the neurologic examination the patient fainted and examination of blood pressure in the recumbent and erect postures revealed the existence of orthostatic hypotension.

In the recumbent position the blood pressure averaged 160/110, a heart rate of 84. In the erect posture at the end of one minute of standing the blood pressure was 60/50, with a heart rate of 140. The patient was unable to stand for periods longer than three minutes without falling as a result of syncope. The Flack test gave markedly positive results. Detailed vascular examinations were conducted over a period of three days and very severe orthostatic tachycardia and hypotension of the degree already noted were found on every occasion. During this period of control the hematocrit estimation was 36 and studies of blood volume conducted by means of the congo red method demonstrated a total volume of 2,585 cc. of plasma or 45 cc. per kilogram of body weight. The total volume of whole blood was 4,038 cc. or 70 cc. per kilogram of body weight.

The patient was then placed on the tilted "head-up" bed with the head of the bed elevated 18 inches. The patient was encouraged to sit in a chair for as long as possible during the daytime and was forbidden to lie on a flat bed. During the course of three days no change could be detected in symptoms or in the signs of tachycardia or hypotension. On the fourth day, coincidental with the appearance of slight edema of the lower extremities, the clinical picture changed dramatically. In the recumbent position the blood pressure was 164/94, with a pulse rate of 80. With the patient in the erect posture, at the end of one minute the blood pressure was 166/98, with a heart rate of 96. At the end of ten minutes of continuous standing the blood pressure was 138/92, with a heart rate of 104. At the end of a half hour of continuous standing the blood pressure was 120/80, with a heart rate of 116. The patient was able to walk alone without assistance for the first time since admission to the hospital.

She was then placed on a flat bed for ten minutes, and studies of blood volume were conducted. The hematocrit index was 34. The total volume of plasma was 2,930 cc. or 51 cc. per kilogram of body weight. The total volume of whole blood was 4,448 cc. or 78 cc. per kilogram of body weight. There had been an apparent increase of 410 cc. in the volume of whole blood. Immediately after the determinations of blood volume were made, the patient was again placed on the tilted bed regimen. The improvement in symptoms, heart rate and blood pressure with the patient in the erect position was maintained.

In view of the fact that the patient had received three injections of liver parenterally at the time of her first admission to the hospital, the improvement could not be ascribed alone to the tilted bed. To evaluate the effect of the tilted bed the patient was placed on a flat bed for forty-eight hours. During the first twenty-four hours no appreciable change could be noted in the heart rate or blood pressure with the patient in the erect posture. At the end of forty-eight hours coinciding with the disappearance of the slight edema of the lower extremities the patient reverted to her previous condition. She was unable to stand for periods longer than a minute without syncope. The blood pressure with the patient recumbent was 140/80, with a heart rate of 80 beats per minute. Blood pressure in the erect posture at the end of half a minute was 60/45, with a heart rate of 130. The patient was again placed on the tilted "head-up" regimen and within forty-eight hours had completely regained postural vascular adaptability and was able to walk without assistance. During the course of three weeks of observation in the hospital she has remained on the tilted bed regimen and has not had a syncope episode. The blood pressure and heart rate have remained consistently normal when she stands. With her increased ability to exercise, the edema of the lower extremities has disappeared. The signs of subacute combined sclerosis are still present. In spite of extensive liver parenterally administered the patient's blood picture has remained unchanged. The concentration of hemo-

globin is 8.1 Gm. per hundred cubic centimeters of blood. The erythrocytes number 4,100,000 per cubic millimeter of blood. Examination of the blood smear reveals hypochromic microcytic anemia with an occasional macrocyte.

An interesting feature of this case is the patient's history of twenty years of exhaustion and syncopal episodes. Every morning in these twenty years she had experienced severe exhaustion and dizziness during the first two hours after arising from bed. She had warned her class in school not to be concerned if they saw her put her head on her desk to keep from fainting. For twenty years she had not dared to kneel or stand in church for fear of fainting. During the afternoons and evenings of these twenty years the exhaustion would disappear and her tendency to faint would vanish, only to reappear again the following morning, after a night's rest in bed. Since institution of the tilted bed regimen the morning exhaustion, faintness and tendency toward syncope have disappeared in spite of the presence of subacute combined sclerosis. This patient was observed six months later. She had been treated persistently with liver extract and had slept on the "head-up" bed. The anemia and symptoms of subacute combined sclerosis were greatly improved. Orthostatic hypotension was absent but she stated that when she slept on a flat bed symptoms of this condition recurred.

COMMENT

It appears that there is an inherent defect in the ability to return venous blood to the heart when patients stand, in the syndromes of primary orthostatic hypotension and orthostatic tachycardia as well as in cases of secondary orthostatic hypotension following extensive sympathectomy for essential hypertension. This defect in the "potential" of venous return can be demonstrated objectively by means of the Flack test.

The tilted "head-up" bed has improved significantly the ability of the circulation of these patients who have orthostatic hypotension and orthostatic tachycardia to adapt itself to the erect posture as shown by objective study of the cardiac rates and blood pressures in the erect posture. These studies have corroborated the marked subjective improvement which follows this type of therapy. The improvement is maintained if use of the tilted bed at night is continued. Rest on the ordinary flat bed for a night or for several nights is sufficient to cause a reversal of the patient's condition and reestablish the original pattern of vascular maladaptation characterized by orthostatic tachycardia and hypotension and by recurrence of symptoms. Some patients with orthostatic tachycardia and orthostatic hypotension are not benefited by this type of treatment. The reasons are obscure.

It appears that rest and sleep on the tilted bed have prevented loss of that measure of postural adaptation which the patient himself has gained during the daytime, by some physiologic process attendant on increased activity in the erect posture. Whether this gain results from readjustments of activity of the autonomic nervous system to the muscles in the walls of the veins, whether there is a change in the tone of striated muscle, an increase in the content of extracellular fluid in the extremity, an increase in the volume of circulating blood or an intrinsic increase in venous or capillary tone is at the present time impossible to say. Investigation now being conducted suggests that the improvement in postural vascular adaptability coincides with an increase in the volume of circulating blood and a definite increase in the content of extracellular fluid in the lower extremities. It would seem logical to assume that the increased pressure of extracellular fluid would prevent in some degree pooling of blood in the legs with the patient in the upright position. We make the tentative suggestion that the content of extracellular fluid in the lower extremities

is increased by the "head-up" posture and prevents pooling of venous blood in the legs as a result of increased tissue pressure. Return of venous blood to the heart is thus maintained in a fashion approaching normal. Studies are being conducted at the present time to determine the value of the "head-up" bed in cases of hypertensive headache, nocturnal epilepsy, exhaustion syndromes during convalescence and other disabilities that are associated with definite postural features.⁷

CONCLUSIONS

Elevation of the head of the bed for some patients with orthostatic tachycardia and for some patients with orthostatic hypotension prevents acceleration of the pulse rate and decrease in blood pressure when such patients stand. There is a coincidental improvement in symptoms. The "head-up" bed is in our experience the most satisfactory method of treatment for orthostatic tachycardia and orthostatic hypotension.

ABSTRACT OF DISCUSSION

DR. HORACE M. KORN, Iowa City: The idea that the cause of orthostatic hypotension is to be sought in a disturbance of the mechanisms which normally provide, under all conditions, an adequate flow of blood from the veins to the heart is new, as far as I know, and is certainly attractive. Furthermore, it seems to me that likening the mechanism to that of nitrite shock is quite reasonable. Although, naturally, a larger series of cases will have to be collected before final conclusions can be drawn, the results obtained in these two cases by having the patient sleep with his head slightly elevated, which, theoretically, would tend to increase venous tone, strongly suggest that the authors' conception of the pathologic physiology of orthostatic hypotension is correct. I cannot help feeling, however, that hypotension alone is not the sole cause of the symptoms in this disease. After long observation of a typical case, Dr. W. L. Randall and I came to the conclusion that maintaining the blood pressure at an essentially normal level, which we were able to do by means of parendrine, was not enough in itself to relieve the patient of the lassitude and fatigability which are so characteristic. Only when, in addition, we produced psychic stimulation by giving amphetamine sulfate were the subjective manifestations dispelled. Patients with orthostatic hypotension may be subject to spontaneous hypoglycemia, as our patient was, and, if this complication is not recognized whenever it occurs, our efforts to evaluate any form of therapy may be confounded.

DR. O. P. J. FALK, St. Louis: The authors' significant observations are so definite and clearcut that they need little comment. This syndrome has had little light cast on it since the original observations of Bradbury and Eggleston in 1925. My interest in this syndrome was stimulated by observations on some sympathectomized hypertensive subjects on whom the usual phenomena of postural hypertension were observed. It seemed that there were a good many people who had not been sympathectomized but who had somewhat similar symptoms, and on checking postural blood pressure observations on them I was able to confirm the fact that there were a good many subclinical cases of postural hypotension going about unrecognized. I, like Drs. MacLean and Allen, have observed that these people respond to some of the drugs that they have mentioned, including amphetamine sulfate, neosynephrin and parendrine, but not to any permanent or sustained degree. Parendrine (20 mg. once or twice daily) seems to have the most marked and best sustained pressor effect. I wish to make a plea for a little more careful observation on some of these people who complain of such symptoms as undue fatigability and weakness or unsteadiness on standing, by checking their blood pressures in the stand-

7. Since this paper was written five additional patients with orthostatic hypotension and nineteen patients with orthostatic tachycardia have been treated on the "head-up" bed. Marked reversible improvement resulted in four of the cases of orthostatic hypotension and in sixteen of the cases of orthostatic tachycardia. Ten patients with chronic daily morning headaches have been studied. Six of these patients have obtained specific relief from pain in the head by the use of the "head-up" bed at night.

ing as well as the sitting and lying positions, so that these subclinical types will be recognized.

DR. A. R. MACLEAN, Rochester, Minn.: Several of our patients with orthostatic tachycardia have given histories suggestive of hypoglycemic episodes. Fasting blood sugar estimations, sugar tolerance curves and prolonged periods of fasting have definitely ruled out any primary hypoglycemic pathogenesis. However, blood sugar estimations in the lower range of normal values are not uncommon among individuals with tachycardia in the erect posture. This tendency may represent another phase in the disturbed physiology which results in a diminution of the venous return "potential." I wish to emphasize two important features of our work. We have very definite clinical proof that the "head-up" bed has accomplished a return of a large portion of postural vascular adaptability in patients with orthostatic hypotension and tachycardia. It has not cured them. We do not know how this improvement has been brought about. Some of our cases show an actual increase in the circulating blood volume following therapy. All of our cases appear to have an increase in the extracellular fluid content of the lower extremities. We can only say that the use of the head-up bed appears to have accomplished a relative increase in the circulating blood volume as compared to the total cross section of the vascular bed.

Clinical Notes, Suggestions and New Instruments

SUCCESSFUL SUBLINGUAL THERAPY IN ADDISON'S DISEASE

EVELYN ANDERSON, M.D., WEBB HAYMAKER, M.D.
SAN FRANCISCO

AND
EDWARD HENDERSON, M.D.
BLOOMFIELD, N. J.

Desoxycorticosterone acetate has been found highly effective in the treatment of Addison's disease. It is generally given in oil by subcutaneous or intramuscular injection but is being employed also in the form of pellets implanted under the skin. The latter method of administration is a precarious one, since there is no way of controlling dosage; excessive absorption of the active principle from pellets, as manifested by edema and anasarca, elevation of blood pressure to hypertensive heights and occasionally fatal circulatory collapse, has been reported by Loeb¹ and others. Subcutaneous and intramuscular injections, on the other hand, allow control of the dose administered, but they are often a source of great inconvenience and no little expense.

The ingestion of tablets of desoxycorticosterone acetate is for practical purposes valueless. Two of our patients with Addison's disease who ingested ten times the dose of desoxycorticosterone acetate effective by the subcutaneous route developed symptoms of adrenal cortical insufficiency. Kuizenga, Nelson and Cartland² have shown in experiments on the rat that this substance is less than one thirty-fifth as effective orally as parenterally.

In connection with this problem of an effective oral form of desoxycorticosterone acetate which would be rapidly absorbed, it was concluded that, since the ranine veins and ranine artery—besides the mass of capillaries and available lymphatics—are so near the surface and so exposed as to be more readily available for absorption of a substance when applied topically

than any other part of the body, sublingual administration of steroids in solution appeared to be entirely practicable.

It was found that desoxycorticosterone acetate dissolved in propylene glycol administered by drops under the tongue was as effective in the cases herein reported as when given in oil subcutaneously or intramuscularly. Each cubic centimeter of propylene glycol contained 10 mg. of desoxycorticosterone acetate. The dropper used by the patients was such that 1 cc. of the solution was discharged as 40 drops. Hence 4 drops contained 1 mg. of desoxycorticosterone acetate. The dose was adjusted to the needs of the patient, from 8 to 24 drops of the solution, or 2 to 6 mg. of the active substance, being given daily in divided doses.

All six patients who have been receiving desoxycorticosterone acetate sublingually for from six to eight weeks are in excellent condition and are carrying on their usual occupations. A brief report of the status of these patients follows:

REPORT OF CASES

CASE 1.—H. E. L., a man aged 29, had had the characteristic signs and symptoms of Addison's disease since 1936. His usual weight of 135 pounds (61 Kg.) had fallen to 112 pounds (51 Kg.). A diffuse bronze pigmentation of the skin and of the buccal and pharyngeal mucous membranes was noted. Blood pressure ranged from 90 systolic, 40 diastolic to 100 systolic, 60 diastolic. Roentgenograms in 1936 failed to reveal any changes in the adrenals and lungs.

From April 1937 to September 1939 the patient was treated with various preparations of adrenal cortex extract. For about a year thereafter he received desoxycorticosterone acetate from 2.5 to 5 mg. intramuscularly once daily. By Aug. 22, 1940, his weight had increased to 123 pounds (56 Kg.), his blood pressure was 95 systolic, 60 diastolic and he felt well but, as during the past four years, he was unable to carry on his occupation. At that time sublingual administration of desoxycorticosterone acetate in propylene glycol was started, 4 drops being given five times a day (or 5 mg. of desoxycorticosterone acetate). He was instructed to take a well balanced diet and to discontinue the use of additional salt. When last seen, October 12, the patient weighed 127½ pounds (58 Kg.), his blood pressure was 95 systolic, 80 diastolic, and for the first time in four years he was carrying on his occupation as a ship inspector.

CASE 2.—M. L. M., a man aged 23, entered the hospital on June 18, 1940, his chief complaints being lassitude and extreme fatigability. Within a year his weight had fallen from 185 to 152 pounds (84 to 69 Kg.). A craving for salt had developed during the preceding three months. His blood pressure was 80 systolic, 60 diastolic and his skin showed deep pigmentation. Roentgenograms disclosed no abnormalities in the adrenal regions or the lungs.

Marked subjective improvement followed the administration of 10 mg. of desoxycorticosterone acetate once daily. His blood pressure had increased by July 16 to 110 systolic, 60 diastolic. Because of the development of edema at this time the dose of desoxycorticosterone acetate was decreased to 5 mg. a day. After the disappearance of edema the patient weighed 158 pounds (71.7 Kg.). Sublingual administration of desoxycorticosterone acetate in propylene glycol was started on August 27, the daily dose being 24 drops of the solution (containing 6 mg. of desoxycorticosterone acetate); at that time his blood pressure was 102 systolic, 60 diastolic and his weight 159½ pounds (72.3 Kg.). When the patient was last seen, October 10, he felt exceedingly well despite working long shifts as a taxicab driver. His weight was 165 pounds (75 Kg.) and his blood pressure 118 systolic, 80 diastolic.

CASE 3.—Baby R. M. (patient of Dr. H. E. Thelander), a boy born on Nov. 18, 1939, had symptoms of adrenal insufficiency dating from the time of his birth. The umbilical cord had been thrice encircled about the neck; cyanosis was marked and remained so for three days. On the eighth day after birth the baby vomited and had diarrhea. He responded well to the subcutaneous injection of salt solution and intravenous dextrose.

From the age of 5 weeks the baby received daily 1 mg. of desoxycorticosterone acetate by injection as well as adrenal cortex extract by mouth. His formula was made up with physiologic solution of sodium chloride. Temporary discon-

From the Institute of Experimental Biology and the Department of Medicine, University of California Medical School, and the Medical Research Division, Schering Corporation, Bloomfield, N. J.

The desoxycorticosterone acetate was supplied by the Schering Corporation for this study. The propylene glycol solution was made in our own laboratory. The crystalline material was added to the propylene glycol, which contained 10 per cent by volume of ethyl alcohol, and the material brought into solution by gentle warming. The alcohol was used to increase the solubility of the desoxycorticosterone acetate.

1. Loeb, R. F.: Adrenal Insufficiency, *Bull. New York Acad. Med.* 16: 347-367 (June) 1940.

2. Kuizenga, M. H.; Nelson, J. W., and Cartland, G. F.: Comparative Parenteral and Oral Assays of Adrenal Cortical Hormone Substances, *Am. J. Physiol.* 130: 298-303 (Aug.) 1940.

tinuance of the endocrine therapy was followed swiftly by signs of impending collapse. At the end of nine months the baby had gained well and reacted normally. On Aug. 25, 1940, sublingual use of desoxycorticosterone acetate in propylene glycol was begun, the dose being 2 drops five times a day (daily total of the substance, 2.5 mg.). After about seven weeks on sublingual therapy the baby is "strong and husky."

CASE 4.—D. J. W., a man aged 60, was admitted to the hospital on Aug. 19, 1940, in a state of collapse. He had had attacks of nausea and vomiting and pains in the abdomen for a period of two weeks. Considerable weight had been lost. His skin was deeply pigmented. The systolic blood pressure measured 90; the diastolic pressure could not be ascertained. Roentgenograms disclosed several rounded calcified foci in the lungs but no evidence of a change in the adrenals. The response to desoxycorticosterone acetate injected intramuscularly was highly satisfactory. At the time of discharge from the hospital, on September 5, the patient was receiving 5 mg. of desoxycorticosterone acetate daily.

When sublingual administration of desoxycorticosterone acetate in propylene glycol was begun on September 8 the patient felt well, his blood pressure was 115 systolic, 80 diastolic and his weight was 162 pounds (73.5 Kg.). The daily dose of the solution was 20 drops (or 5 mg. of the substance). On October 10 the patient stated that he felt very well and was fully able to carry on his occupation as a teacher. His blood pressure was 138 systolic, 80 diastolic and his weight 167 pounds (75.7 Kg.).

CASE 5.—S. K. (patient of Drs. Blair Holcomb, E. M. Burns and Hans Lisser), a man aged 35, since July 1937 had had attacks of nausea, vomiting and diarrhea which passed for "intestinal influenza." Following such an attack in 1938 the patient lost 30 pounds (13.6 Kg.) within a month. In July 1939, when seen by Drs. Holcomb and Burns, the patient presented a careworn and exhausted appearance, his skin was moderately pigmented, his blood pressure was 116 systolic, 80 diastolic, and he weighed 154 pounds (70 Kg.). He was given adrenal cortex extract subcutaneously and abundant salt by mouth. From Aug. 28 until Sept. 5, 1940, while under Dr. Lisser's care, the patient received desoxycorticosterone acetate intramuscularly 5 mg. a day and salt by mouth. He improved subjectively and his blood pressure rose to 140 systolic, 110 diastolic.

Since September 5 the patient has been taking desoxycorticosterone acetate in propylene glycol sublingually, 4 drops of the solution five times a day (a total daily dose of 5 mg. of the substance). On October 15 he weighed 152 pounds (69 Kg.), his blood pressure was 120 systolic, 86 diastolic, he appeared to be somewhat less pigmented and he stated that he felt better generally.

CASE 6.—Mrs. M. S. (patient of Dr. Helen Lee), aged 38, had had tuberculous peritonitis in 1927. In May 1938 she experienced a feeling of great fatigue and at about the same time noted that her skin was becoming pigmented. By April 1939 the tendency to fatigue had become more marked and there were occasional bouts of diarrhea. Roentgenograms disclosed a small calcified body overlying the upper pole of the left kidney. The blood pressure was 90 systolic, 50 diastolic and she weighed 131 pounds (59.4 Kg.). Impending collapse was prevented by the administration of adrenal cortex extract together with sodium chloride and sodium citrate. Since then she had taken adrenal cortex extract by mouth and by injection, together with large amounts of sodium chloride.

On Aug. 19, 1940, the sublingual use of desoxycorticosterone acetate in propylene glycol was begun. As in the other instances herein reported, the patient was instructed not to take salt in excess of that of the normal diet. At first 24 drops of the solution (6 mg. of the active substance) was given sublingually each day, but later, because of the development of edema about the ankles, the daily dose was reduced to 20 and later to 16 drops. The patient stated on October 19 that she felt considerably better on this regimen than she had heretofore and that she could now carry on her household and social activities without undue effort. On that day she weighed 140 pounds (63.5 Kg.) and had a blood pressure of 110 systolic, 80 diastolic.

SUMMARY

Desoxycorticosterone acetate dissolved in propylene glycol and administered by drops under the tongue has been found to be an effective form of replacement therapy in Addison's disease. The desoxycorticosterone acetate so administered seems to be as effective as that given in oil subcutaneously or intramuscularly.

Studies are now in progress as to the absorption of various endocrine substances when administered sublingually, particularly androgens and estrogens.

CHERRY STEM IN COMMON DUCT STONE

CONRAD J. BAUMGARTNER, M.D., AND IRVING I. LASKY, M.D.
LOS ANGELES

Foreign bodies are rarely considered a nucleus for stones found in the biliary tract. When encountered, however, they do present some interesting speculations.

REPORT OF CASE

A Negro youth aged 20, a student, admitted to the Los Angeles General Hospital Feb. 26, 1940, had been ill for ten days with nausea, vomiting and a sharp pain in the right upper quadrant of the abdomen. On the fifth day it was noted that he had acholic stools and also that he was jaundiced. He had a fever at times but no chills. There had been no antedating history of food intolerance or of similar attacks.

He was well developed and well nourished and in no great pain. The skin and scleras were jaundiced. There was rigidity in the right upper quadrant of the abdomen. Physical examination otherwise was negative. The hemoglobin content was 108 per cent, the erythrocyte count was 4,650,000 and the leukocyte count 13,400, with 83 per cent neutrophils, 3 per cent monocytes and 10 per cent lymphocytes. The urine gave a positive reaction for bile. The icteric index was 73. A flat x-ray plate of the abdomen was negative. His condition improved rapidly and he was discharged from the hospital March 7, only to return two days later with a recurrence of the same symptoms. He was again treated symptomatically and the condition rapidly cleared up again. March 21, a gallbladder dye study was made. There was no definite dye concentration: radiopaque calculi were not noted. He was discharged March 25. He felt well except for varying degrees of pain in the right upper quadrant and a poor appetite until May 22, when the pain again became severe and he reentered the hospital the following day.

His temperature was 103 F. and the blood pressure 105 systolic, 75 diastolic. He was in great pain, his face was flushed and the scleras were mildly icteric. There was rigidity of the right upper quadrant of the abdomen and the liver was palpable three fingerbreadths below the costal margin. The erythrocyte count was 4,500,000 and leukocyte count 13,100, with 86 per cent neutrophils. The icteric index was 40 on May 27 and 67 on May 30. He had an afternoon temperature of from 101 to 102 F. and stools were light yellow to gray until June 5, when he again became afebrile and asymptomatic.

At this time it was felt that an exploration should be done. Preoperative laboratory examination showed a cholesterol level of 208 mg. per hundred cubic centimeters of blood, a normal prothrombin content and an icteric index of 20, and oral cholecystography again showed no dye concentration.

July 1 a laparotomy was performed (by a preceding service). The gallbladder was reported as "only slightly thickened and almost normal in appearance" by the surgeon but found to contain very small flaky stones. The common duct was opened and some of the same material found. A catheter was placed in the common duct and the gallbladder removed. He made an uneventful recovery and on July 9 a cholangiogram revealed moderate dilatation of the intrahepatic ducts. There was a smooth 1.5 cm. ovoid shadow in the distal end of the common duct about which a small amount of dye could be forced. These conditions were consistent with an impacted stone at the distal end of the common bile duct. Several methods of flushing the

From the surgical service, College of Medical Evangelists, and the Los Angeles General Hospital.

duct, after attempted fragmentation of the stone with ether, were attempted. Atropine, glyceryl trinitrate, desoxycholic acid and magnesium sulfate were of no avail, as the shadow persisted. The prothrombin time was checked and found normal.

July 29 exploration was done (by C. J. B.). The common duct was fixed in edematous adhesions from the previous operative procedure. It was explored but only flakes of stony material were obtained. The retroduodenal portion was then explored by mobilization of the duodenum according to the method of Kocher. The common duct was noted to traverse intrapancreatically and in that portion a fairly large stone could be readily palpated with the palm of the left hand behind the second portion of the duodenum. The stone was firmly lodged near the anterior surface of the pancreas and therefore was attacked through an anterior transpancreatic approach. With the palm of the left hand behind the duodenum and with upward pressure against the stone by the index finger behind the pancreas, careful separation was made of the pancreas over the stone, the duct incised and the soft stone dislodged in pieces. Large amounts of stony material were washed out. With expulsion of the central fragments a foreign body extruded. This had a bulbous tip at one end and resembled in size and shape a partly decomposed cherry stem (shown in illustration). Catheters were sutured into the common duct openings. The patient made an uneventful recovery.

Dr. H. E. Evans, pathologist at the Los Angeles General Hospital, reported that the foreign body was a black structure

Foreign body and some of the fragments of stone removed from the common duct (twice natural size.)

2.5 cm. long and 2 mm. in width and less than 1 mm. in thickness and had the appearance of some sort of vegetable or plant matter. A section was submitted to Dr. E. M. Hall, professor of pathology at the University of Southern California School of Medicine. His report stated that sections showed a number of small bits of moderately woody plant tissue and that many tracheal ducts were present with fairly thick walls.

The patient was a bright chap, a student of chemistry at the University of Southern California, and during his convalescence we asked him whether he had knowledge of ever eating cherries, stem and all. He replied that cherries had always been his favorite dish and that in earlier youth he had often eaten them by the double handful, at times not paying too much attention to stem or stone. We felt that we were safe in assuming that this was a cherry stem which had been ingested and by accident had slipped up the ampulla and had become lodged in the common duct, in time to become the nucleus for a stone.

COMMENT

Foreign bodies in the biliary tract are seldom encountered and are indeed a curiosity. A recent article by Toland¹ reviews the literature quite thoroughly. Among some of the foreign bodies removed from the common duct were swabs, rubber drains and nonabsorbable catgut ligatures, all from previous operations. As a nucleus for stones, pieces of suture were found most frequently, followed by an incidence each of bristle,

thread and a piece of rubber drain. There are two reports of swallowing and migration: one a piece of wire and the other the handle of a spoon.

It is quite likely that if the centers of all single common duct stones were examined, particularly those occurring in apparently normal gallbladders without stones, the presence of a foreign body would be encountered at least occasionally.

GLANDULAR PHYSIOLOGY AND THERAPY

THE ANTERIOR LOBE OF THE HYPOPHYSIS IN INTERMEDIARY METABOLISM

DAVID L. THOMSON, PH.D.

Professor of Biochemistry, McGill University
MONTREAL, CANADA

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—Ed.

The role of the anterior lobe of the pituitary in intermediary metabolism, especially in carbohydrate metabolism, has been reviewed by Houssay,¹ Russell,² Long,³ Van Dyke,⁴ Young,⁵ Thomson and Collip⁶ and others in recent years, in greater detail and with fuller bibliography than is possible in these pages. The subject is one of the greatest difficulty and complexity, since it is seldom possible to tell how widely the repercussions of any experimental interference may spread through the endocrine system. Great variations in behavior between species and between individuals in any one species are the rule rather than the exception. None of the anterior pituitary principles has yet been obtained in a state of indubitable purity, and any extract of the gland may or may not, depending on the source and the method of preparation, contain not only the thyrotropic and the corticotropic (adrenotropic) hormone (which must secondarily influence metabolic processes in many ways), the growth-promoting hormone (which presumably promotes anabolic processes even if its primary influence is on skeletal growth) and prolactin (which may directly or indirectly control metabolic adaptations to lactation) but also an uncertain number of principles active in metabolism but less clearly defined

at present. For example, O'Donovan and Collip⁷ demonstrated the existence of a factor which rapidly elevates the metabolic rate and depresses the respiratory quotient in normal and in thyroidectomized rabbits and guinea pigs and which is apparently derived from the pars intermedia, being closely associated with the melanophore-expanding hormone. Extracts which contain this factor may be largely freed from the "accepted" pituitary substances by exposure to high temperatures and still display manifold effects on intermediary metabolism. Even true posterior lobe principles (known and unknown) may be present in so-called anterior pituitary extracts, and may be overlooked.

A comparatively simple example of the apparent contradictions which abound in this field of study may be given. The hypophysectomized animal, with its atrophic thyroid, has a low metabolic rate, and its peripheral tissues consume abnormally small amounts of dextrose at all blood sugar levels⁸; in other words, its tolerance for injected dextrose is low,⁹ but since the rate of absorption from the intestine is also greatly reduced, the tolerance for orally administered sugar is high.¹⁰

FASTING HYPOGLYCEMIA AND THE GLYCOSTATIC PHENOMENON

Many observers have noted that when hypophysectomized animals of any species are caused to fast, the blood sugar falls rapidly to levels dangerously low. In hypophysectomized monkeys, for example, after eighteen hours' fast the blood sugar averaged 59 mg. per hundred cubic centimeters, while in normal animals it was still 110 mg.;¹¹ and in rats, whose metabolism is more intense, the blood sugar concentration may be halved in eight hours' fasting after hypophysectomy, whereas controls show only a 20 per cent decrease.¹² Many hypophysectomized animals have died in hypoglycemia, and many have been dramatically resuscitated from a cold and deathlike torpor by injections of dextrose.¹³ The phenomenon is not ascribable to a breakdown of the mechanism of glycogenolysis, since the stores of liver glycogen usually show similar rapid exhaustion. It has been claimed¹⁴ that injected thyroxine will maintain the blood sugar of hypophysectomized animals during fasting, but it is more widely believed that the tendency to hypoglycemia is a consequence of the atrophy of the adrenal cortex which follows hypophysectomy, since adrenalectomized animals also show this tendency, especially if their mineral metabolism is con-

trolled, and since injected cortical steroid substances will protect both hypophysectomized and adrenalectomized animals against it.¹⁵

Two rival interpretations of the hypoglycemic tendency have been put forward. On one hand, it is urged that the hypophysectomized (or adrenalectomized) animal prefers carbohydrate as a fuel and is spendthrift of its stores thereof. Evidence for this is seen in experiments in which dextrose is administered orally to rats which have fasted for twenty-four hours; the normal rat will oxidize about half the dextrose administered (in the following four hours) and will store about one third of it as liver and muscle glycogen in roughly equal shares, but the adrenalectomized or hypophysectomized rat will oxidize more and store less, whereas administration of adrenal cortex extract increases storage.¹⁶ On the other hand, hypoglycemia may be an indication that the supply of new carbohydrate by glyconeogenesis is lagging behind the demands of the peripheral tissues. That the supply is, in fact, reduced after hypophysectomy is indicated by an analysis of blood leaving the liver;¹⁷ furthermore, if one makes the orthodox assumption that a large and fairly constant proportion of the amino acids liberated in the breakdown of tissue protein constitutes the main source of new carbohydrate for the fasting animal, the excretion of nitrogen becomes a measure of the intensity of glyconeogenesis and shows the latter to be restricted after hypophysectomy. During fasting the nitrogen excretion tends to be low,¹⁸ and is raised by the hormones of the adrenal cortex when they maintain the blood sugar level;¹⁶ the increase in nitrogen excretion and in stored carbohydrate which occurs when rats are exposed to low atmospheric pressures is not seen after extirpation of the hypophysis or of the adrenal cortex.¹⁹ There is, then, fair if not conclusive evidence that the fall in blood sugar and liver glycogen in fasting hypophysectomized animals indicates that a decrease in the production of hormones in the adrenal cortex has made impossible acceleration of the protein breakdown to a point at which glyconeogenesis would be adequate; and in any case the protective action of anterior pituitary extracts may be ascribed tentatively to the corticotrophic factor which they contain.²⁰

But the fasting hypophysectomized rat or mouse (other species have hardly been examined) shows a decrease in muscle glycogen which is more striking and appears more rapidly after extirpation of the gland than that in adrenalectomized animals; moreover, anterior pituitary extracts may display a "glycostatic" power to retard this decrease even when they contain little corticotrophic substance and even in rats which have been adrenalectomized as well as hypophysecto-

mized.²¹ During an eight hour fast the concentration of muscle glycogen may fall from 0.55 to 0.50 per cent in a normal rat and from 0.50 down to 0.30 per cent in a hypophysectomized rat; the higher respiratory quotient of the latter shows that the vanished carbohydrate has been oxidized, while the nitrogen excretion affords no evidence that glyconeogenesis diminished.²² It is tempting to speculate that this using-up of muscle glycogen is due to a deficiency in the supply to the peripheral tissues not merely of dextrose, as in the adrenalectomized animal, but also of some other fuel (acetoacetic acid, for example; in which case this might be the inverse of the ketogenic phenomenon discussed later), but there is no supporting evidence at present for any such interpretation. It must be noted also, as a type of synergism yet unexplained, that the glycostatic phenomenon is most easily obtained when adrenal cortical principles are present in quantity, though it does not require that the gland itself should be intact.²⁰

SENSITIVITY TO INSULIN AND THE GLYCOTROPIC PHENOMENON

The extreme sensitivity of the hypophysectomized animal to insulin, observed by Houssay and Magenta²³ in the dog, has been confirmed in many other species; it is from ten to thirty times greater than that of intact animals, the hypoglycemia being both intense and prolonged. Some increase in sensitivity is also observed in animals deprived of their adrenal medullae or of the sympathetic nervous system or even of the thyroid gland; but these observations seem irrelevant in face of the fact that pretreatment with suitable anterior pituitary extracts may decrease the exaggerated response to insulin of the hypophysectomized animal²⁴ and completely prevent insulin hypoglycemia in the normal animal;²⁵ this is called the "glycotropic" effect. In attempting an interpretation one must bear in mind that extracts showing glycotropic activity do not raise the blood sugar level or affect carbohydrate stores in normal animals, do not prevent the development of hypoglycemia in fasting hypophysectomized animals²⁶ and do not retard the fall in blood sugar that follows hepatectomy in the rabbit (though they prevent further acceleration of this fall by insulin²⁷). Hence the factor is not a general inhibitor of carbohydrate consumption but a rather specific "anti-insulin"; yet any chemical interaction between these agents is unlikely, since the

glycotropic factor must be administered some hours before the insulin to be effective. Part of the sugar which disappears from the blood under the influence of insulin is laid down in the muscles as glycogen, and it is possible that the glycotropic factor prevents this.²⁶ Beyond this the attempt at interpretation becomes frankly speculative; one could, for instance, work out a hypothesis equating the glycotropic and ketogenic effects, while, on the other hand, Jensen and Grattan^{25d} produced evidence that the glycotropic and corticotropic factors are identical.

It was formerly thought that hypophysectomized animals were resistant to the hyperglycemic action of epinephrine and that this might explain their sensitivity to insulin, but it is only when the solution of epinephrine hydrochloride is injected subcutaneously that the sluggish circulation of the hypophysectomized animal, with its atrophic thyroid, prevents epinephrine from acting with its usual vigor.²⁸ Pretreatment with certain pituitary extracts diminishes the response to epinephrine; this is due to the presence of an unidentified factor probably originating in the posterior lobe.²⁹

EFFECT OF HYPOPHYSECTOMY ON PANCREATIC DIABETES

No discovery has more sharply focused attention on the role of the anterior lobe of the hypophysis in carbohydrate metabolism than that of Houssay and Biasotti,³⁰ who showed, first in toads and then in dogs, that hypophysectomy profoundly modifies and moderates the intense diabetes usually produced by complete pancreatectomy; this discovery has been repeatedly confirmed and extended. Survival without insulin is greatly prolonged, and the animals are as likely to die in a hypoglycemic crisis as from diabetes; glycosuria and hyperglycemia do not become extreme, and are controlled by small amounts of insulin; ketosis is slight or absent; metabolic rate and nitrogen excretion do not show the usual increase, and weight is lost slowly if at all; liver glycogen stores are quite well maintained, and although the tolerance to administered dextrose is quite low,³¹ excretion is not quantitative, and the respiratory quotient is not pegged at the fat level, while during fasting the low values of the urinary dextrose-nitrogen ratio indicate that much of the carbohydrate produced by glyconeogenesis is being consumed.

Long and Lukens^{32a} showed in cats and dogs that adrenalectomy affected pancreatic diabetes in much the same way as hypophysectomy did in Houssay's experiments, and they proved that it was the cortex rather than the medulla of the adrenal which was of importance. Their animals received cortical extract in quantities sufficient to prevent serious disturbance of water and salt metabolism but apparently insufficient

to replace the function of the glands in carbohydrate metabolism; in later experiments they found that adrenalectomy abolished glycosuria in partially depancreatized rats, maintained after the second operation with saline solution.³ The effect of thyroidectomy on pancreatic diabetes is slight and inconstant.

Discussion of these adrenal-pituitary relations will be deferred until the action of pituitary extracts on animals doubly operated on has been described, but it may be well to point out here that while in the dog and still more in the cat pancreatectomy alone produces exceedingly severe and rapidly fatal diabetes, there are other species (including pig, sheep and monkey) in which the diabetes is of a relatively mild type, with low dextrose-nitrogen ratios, little ketosis and great sensitivity to insulin—resembling the condition observed in the hypophysectomized-depancreatized, or "Houssay," dog or cat, or clinical diabetes of moderate severity. It is especially interesting to note that cases have been encountered in the clinic in which fibrotic or other change had almost completely obliterated the islet tissue of the pancreas, yet the diabetes resembled that produced by pancreatectomy in the monkey³³ rather than that in the dog, and was less severe than in many other cases of clinical diabetes in which there was little or no pathologic alteration of the islets.

DIABETOGENIC ACTION OF ANTERIOR PITUITARY EXTRACTS

The injection of anterior pituitary extracts of many kinds is not infrequently followed by slight transient hyperglycemia; this has been ascribed to contamination with posterior-pituitary principles or to nonspecific stimulation of epinephrine discharge, and does not in any way merit the name "diabetogenic." But if fresh simple extracts that have been cautiously prepared are administered in large doses day after day to well nourished dogs, cats or rabbits, one may observe in many individual animals after some days a gradual but maintained rise of the blood sugar beyond glycosuric levels, moderate ketonuria, increased excretion of nitrogen and other symptoms of diabetes.³⁴ At its height the condition may simulate in severity that produced by pancreatectomy, from which it differs chiefly in maintenance of body weight, maintenance of liver glycogen and resistance to insulin treatment.⁵ It is interesting to compare this with the resistance to insulin exhibited in those patients with diabetes in whom acromegaly and hyperthyroidism point to hyperfunction of the anterior lobe of the pituitary as the primary disturbance. Yet it must not be supposed that the secretion of insulin continues unimpaired during the temporary diabetes produced by anterior pituitary extracts, for degranulation and hydropic degeneration of the beta cells of the islets of Langerhans occur,³⁵

the amount of insulin extractable from the pancreas falls to a low level,³⁶ and when such a pancreas is transplanted into a diabetic animal it seems to produce little insulin.³⁷ It seems unlikely that the anterior pituitary extract should have a directly harmful influence on the pancreas and more probable that the islets become exhausted because of the tendency of substances in the pituitary extract to elevate blood sugar and neutralize insulin action; similar changes in the islets are observed when blood sugar levels are kept high by injections of dextrose,³⁸ and a supply of extra insulin may protect the islets against the anterior pituitary extract.³⁹

Extracts which are diabetogenic in the dog have no such action in the guinea pig, mouse or rat; in the last, indeed, they cause a considerable increase in the quantity of islet tissue found in the pancreas and in the amount of insulin extractable therefrom;⁴⁰ this "pancreatotropic" effect is not now obtainable in the circumstances in which it was first described.⁴¹ One concludes that in some species the islet tissue is sufficiently adaptable to bear any strain that has yet been thrown upon it.

The type of experimental diabetes described in the foregoing paragraphs is well called temporary. Not merely does it soon subside after the treatment has ceased, but it does not persist for more than a few days even when the injections are continued at a constant level; the diabetic symptoms vanish, though resistance to insulin (glycotropic effect) persists. But an increase in the amount of anterior pituitary extract given will reestablish the diabetic state for a few days more, until finally a dose is reached (say, the equivalent of 25 Gm. of fresh gland daily) at which the animal can no longer escape: the diabetes not only persists as long as treatment continues but reaches a point (often marked by transient exacerbation of ketonuria) at which the degeneration of the islets becomes irreversible, so that the diabetes continues indefinitely and unabated even when the extract is withdrawn.⁴²

Such permanently diabetic dogs vary in the intensity of diabetes exhibited, but in general their insulin requirements, sugar excretion and dextrose-nitrogen ratios are even higher than those usually recorded for depancreatized dogs on the same diet; ketonuria, however, may be low in the early stages, weight is better maintained, and survival without insulin is much longer;⁴³ the islet tissue is altered to a variable extent,

and hardly any insulin can be extracted from it; surgical removal of the pancreas may have little influence, once the permanent diabetes is established. One feels that if there are real differences between dogs that are diabetic because their islet tissue collapsed under treatment with an anterior pituitary extract weeks or months previously and dogs that are diabetic because the whole pancreas has been removed, such differences must be due to the loss of the pancreatic acinar tissue in the latter rather than to persistence of any extrapancreatic effect of the anterior pituitary extract in the former.

ANTERIOR PITUITARY EXTRACTS IN DEPANCREATIZED ANIMALS

It is probably desirable to restrict the term "diabetogenic" to extracts capable of producing temporary if not permanent diabetes in normal dogs,⁵ but it has sometimes been applied in a rather different way. To produce diabetes in normal animals, even in the susceptible individuals of relatively susceptible species, one requires large doses of extracts which have been carefully protected from the destructive action of heat or powerful reagents; but in subtotally depancreatized animals (even of resistant species such as the rat) or hypophysectomized-depancreatized ("Houssay") animals, diabetic symptoms can be elicited easily, or intensified if already present, with moderate doses of extracts of many kinds. The conclusion is inescapable that true diabetogenic potency involves the action of one or more very labile factors as well as of relatively stable factors that may be effective by themselves in animals deprived of all or most of their insulin-producing tissue.

Among these relatively stable factors one may certainly include the corticotrophic principle, for extracts which evoke intense glycosuria and ketonuria in hypophysectomized-depancreatized cats have little or no effect on adrenalectomized-depancreatized animals;^{32a} adrenal cortex extract causes glycosuria in subtotally depancreatized (but not in normal) rats.⁴⁴ But in the latter test the action of the cortical steroids is not as great when they are administered by themselves as when they are administered simultaneously with anterior pituitary extracts (a further example of the type of synergism already discussed²⁰); moreover, anterior pituitary extracts may evoke glycosuria in partially depancreatized adrenalectomized dogs;⁴⁵ hence the corticotrophic factor is certainly not the only one involved. In considering the identity of the labile factor or factors, one naturally thinks of the "growth hormone," which is closely associated with diabetogenic activity;⁴⁶ and it has been shown recently that even brief heat treatment largely destroys the striking power of fresh anterior pituitary extracts to increase the body glycogen of normal fasting mice.⁴⁷ In viewing the diabetogenic phenomenon as a whole one may cite the evidence (quoted in the discussion of the hypoglycemia of fasting animals) that anterior pituitary principles often tend to increase glycogenesis; one may be inclined also to credit them with the power to diminish the utilization of carbohydrate by the peripheral tissues,

even if this seems to elude direct demonstration,¹⁴ and one has, unfortunately, several different unsupported interpretations of the glycotrophic phenomenon to draw on as required.

THE KETOGENIC PHENOMENON

The urinary excretion of acetone bodies by the fasting or fat-fed rat, normally quite small, may be greatly increased by injecting anterior pituitary extracts;⁴⁸ there is a simultaneous rise in blood ketones, which is a more sensitive and dependable index of the phenomenon, since acetoacetic and hydroxybutyric acids are to some extent threshold substances. Parallel observations have been made in other species, including the mouse, guinea pig, rabbit, dog and man. The effect is lessened but not abolished after adrenalectomy.

A general discussion of this phenomenon has been published elsewhere;⁴⁹ there is good evidence that it indicates an increased outpouring of ketone bodies by the liver rather than a diminished utilization of them;⁵⁰ and in general the ketosis is accompanied by a transfer of fat from the depots to the liver, in which large quantities may accumulate.⁵¹ There is accordingly a good deal of support for the view that the phenomenon represents a general stimulation of fat catabolism beyond the capacity of the body to oxidize the ketonic final products. Yet other possibilities exist; fatty acids are not the only conceivable source of acetone bodies, and there may well be different types of ketonemia; if stimulation of fat metabolism does occur, it may be secondary rather than direct.

Shipley and Long,⁴⁶ for instance, have suggested that the primary effect of crude extracts of the anterior lobe may be to retard the breakdown of tissue protein so that the energy requirements of the body are met by drawing on preformed carbohydrate stores (which are rapidly exhausted to the point of hypoglycemia⁵²) and on the fat depots, whose overactive response may produce ketonemia. Some retardation of protein catabolism is, as already pointed out, required of a "growth hormone," and it has in fact been observed in many experiments.⁵³ At first sight this appears to be a bewildering contradiction of the thesis already developed, that anterior

pituitary extracts (especially those containing the corticotropic principle) stimulate protein breakdown and glyconeogenesis, and certainly it is probable that one is here dealing with another factor. It is quite possible that the balance is held by the islets of Langerhans; nitrogen retention will be favored as long as they continue to produce sufficient insulin, nitrogen loss when they break down under the stimulus. Thus Mirsky,⁵⁴ using the rate of increase of nonprotein nitrogen in the blood of nephrectomized dogs to measure the catabolism of protein, finds it to be increased by crude extracts of the anterior lobe in depancreatized (diabetic) animals but slightly decreased in normal ones.

A great deal of effort has been expended in the study of the chemical and physical properties of the factors described and in attempts to separate them by chemical means; the results are of great importance to those actually working in the field but are unfortunately so full of apparent contradictions that they can rarely be used to support general statements and have accordingly been given little attention in this review.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING CHAPTER, WHICH IS THE THIRD OF A SERIES ON AMPUTATIONS AND ARTIFICIAL LIMBS TO APPEAR IN THIS COLUMN. WHEN COMPLETED, THE SERIES WILL BE PUBLISHED IN THE FORM OF A HANDBOOK ON AMPUTATIONS. THE COUNCIL WISHES TO EXPRESS ITS APPRECIATION FOR THE COOPERATION OF ITS GROUP OF CONSULTANTS ON ARTIFICIAL LIMBS. THE COUNCIL IS REPRESENTED BY DRS. FRANK D. DICKSON, HARRY E. MOCK, FRANK R. OBER, S. PERRY ROGERS, PAUL STEELE AND PHILIP WILSON, AND THE ASSOCIATION OF LIMB MANUFACTURERS OF AMERICA IS REPRESENTED BY MESSRS. MCCARTHY HANGER SR., W. E. ISLE, JOSEPH A. SPIEVAK, DAVID E. STOLFE AND J. B. KORRADY.

HOWARD A. CARTER, Secretary.

CHAPTER III. SITES OF ELECTION FOR AMPUTATION

Certain "sites of election" are generally recognized as promising functional amputation stumps, and numerous methods of operation at different sites have been planned with the same objective of function. These sites may be considered in order from below upward.

1. LOWER EXTREMITY

Amputation of toes results only in the slight loss of spring to the gait provided by the final push-off of the toes in each step. The natural weight bearing areas of heel and metatarsal heads are undisturbed, muscular control of the foot is not seriously interfered with, and satisfactory leverage remains. No prosthesis is required.

Amputation through the metatarsals sacrifices the normal weight bearing surfaces beneath the heads of these bones. A plantar flap compensates somewhat by retaining soft tissue integuments physiologically adapted to weight bearing. Muscular control of the ankle is sacrificed no more than in amputation of the toes, although cutting through the short plantar muscles impairs further the support of the arch. Leverage is lost in proportion as the site of amputation progresses backward, and function decreases accordingly. Lisfranc's amputation through the tarsometatarsal joints is as far back as one can go without this loss of leverage becoming prohibitive. It must be remembered that these amputations are usually due to trauma and that the injured tissues seldom allow amputation at this level.

Amputations between the tarsometatarsal and the ankle joints are condemned. Chopart's amputation, leaving only the astragalus and the calcaneus, is the one most commonly employed. Two factors, loss of the natural attachments of the anterior tibial, peroneal and toe extensor muscles and further shortening of the lever of the foot, render equinus deformity of the stump almost inevitable. The appliance for such amputations is as unwieldy and unsightly as that for an amputation just above the ankle, and the resultant function is not so good.

Amputations immediately above the ankle joint are called Syme's or Pirogoff's. In both operations the tibia and fibula are sawed horizontally within 1 inch of the ankle joint. Both employ a posterior flap composed of all the layers of soft tissue from the tip of the heel, and both leave a transverse anterior scar. In Pirogoff's technic the posterior part of the os calcis, sawed vertically, is left in the flap and is opposed to the cut surface of the tibia. Both amputations require careful surgical technic in care of the vessels and nerves and in snug tailoring of the flaps. Neither is likely to succeed in the presence of infection.

Amputations at this level were in high favor a century ago. The patient could frequently walk, or even run, without any appliance. The prosthesis is bulky. It must be entered from the front and laced snugly above the bulbous tip of the stump. It is more serviceable without any ankle joint mechanism. Modern limb manufacturers hold in disfavor any amputation between the heads of the metatarsals and the middle of the leg because of the unsightly appearance of the prosthesis. A recent English compilation of late results in Syme amputations performed during the war of 1914-1918 shows that almost all of these stumps have now been reamputated because of circulatory complications.

The optimum site for amputation in the shaft of the leg is its middle third. In the adult this will vary between 5 and 7 inches from the joint line, depending on the height of the patient and the length of the limb. Longer stumps are apt to be insufficiently covered, to be tender and to suffer vascular difficulties. Longer stumps also require an unsightly bulkiness in the shank of the prosthesis. The shorter stumps, cut through cancellous bone, are likely to permit a larger degree of end bearing, although most of them require that the greater part of the weight be borne on the sloping surfaces of the head of the tibia. The minimum length of tibia for satisfactory leverage is $2\frac{1}{2}$ inches. The fibula should usually be retained for its function in controlling rotation of the prosthesis. In very short stumps it may be removed entirely. If retained it should be cut from 1 to 2 inches shorter than the tibia, depending on the length of the stump. In children the fibula should be cut three inches shorter or else its epiphysis should be arrested. If the fibula is removed, care should be exercised to remove all its periosteum as well.

Amputation through the leg is conveniently performed with the patient prone (face downward). The bones should be denuded of periosteum for a distance of 1 inch and all sharp corners removed, the anterior border of the fibula with a saw and all sharp edges with a rasp. The bones should be covered with a posterior flap composed of the tendinous aponeurosis of the gastrocnemius and fascia with little or no muscle, and in turn by an anterior skin flap long enough to leave a posterior scar. Redundance of flaps must be avoided. Postoperative splinting is especially important to prevent contracture of the knee. Massage, active exercise

54. Mirsky, I. A.: The Influence of the Anterior Pituitary Gland on Protein Metabolism, *Endocrinology* 25:52-56 (July) 1939.

and hardening of the stump are recommended. Early walking on a temporary prosthesis is advantageous.

Amputation by disarticulation at the knee joint, popular a century ago, has fallen into such disuse that it is now generally employed only as a temporary emergency procedure. Objections based on mechanical reasons, such as bulkiness and unsightliness of the prosthesis, and the necessity of disproportionate length of thigh and leg, are unfounded under modern facilities of artificial limb manufacture. Some disarticulation stumps have been unsatisfactory from the functional standpoint for one of two reasons: The patella floating free on the front of the thigh may remain so tender as to prohibit encasement in a socket. Other stumps have permitted painless end bearing at first only to undergo atrophy and ulceration of the terminal integuments after months or years of function.

Theoretically, numerous physiologic and mechanical advantages are apparent at this level. The femoral condyles and the patella, as well as all the soft tissues in an anterior flap, are physiologically adapted to withstanding pressure. Ligation of the popliteal artery below its superior genicular branches leaves a rich anastomosis of vessels at the end of the stump. Retention of the lower femoral epiphysis assures normal growth of the stump in a child. Recent modifications in operative technic, described by Rogers, are directed against the previous faults in these stumps. Arthrodesis of the patella to the front of the femur in its anatomic position eliminates any tenderness and increases the end bearing surface area. Fixation of all the hamstring tendons to the tip of the patellar tendon in the posterior intercondylar notch relieves the terminal soft tissues of tension and subjects them only to pressure, which they are adapted to bear. A limited experience with this technic promises relief from the late complications previously encountered in some amputations at the knee joint.

Amputations through the supracondylar region of the femur are best made with a long anterior flap and a posterior scar. A large degree of end bearing is provided by the osteoplastic method of Gritti-Stokes and by the tendinoplastic methods of Callander and of Kirk. The English experience with a large number of osteoplastic amputations performed between 1914 and 1918 shows that most of these stumps have broken down after some years and been reamputated at a higher level. The composite experience of American limb manufacturers shows that whenever the technical details of the operation were carried out originally the incidence of reamputation has been very small. The tendinoplastic procedures with long flaps and loose closure are particularly suitable in the presence of infection or circulatory impairment. Limb manufacturers prefer to have these stumps 3 inches shorter than the opposite femur for two reasons: to allow room for an internal knee-joint mechanism and to permit the use of a conical socket which can be entered from the top.

The physiologic factors in amputation through the shaft of the femur are similar to those through the leg. Partial end bearing is sometimes possible but most of the weight must be taken on the ischial tuberosity. Sensitiveness to the side pressure of leverage is likely to be less than in the leg because the femur is covered in its whole circumference. Muscles attaching high on the bone exert sufficient voluntary control provided the stump is long enough to transfer that motion. The prosthesis must be suspended from the shoulders or pelvis, and short stumps need a pelvic band. Function

may be limited by the weight bearing surfaces available and by the instability of the flabby stump within the socket.

In amputations through the shaft of the femur the rule is to leave as much bone length as possible. The bone should be denuded of periosteum and rounded off with a rasp, as in the leg. The bone end should be covered with fascia or tendon but not with muscle. An anterior skin flap is best, though it need not be a long one to fall behind the end of the bone. Flaps should be sufficient but not redundant. An artificial limb can be applied at an early date.

In disarticulation of the hip, muscular control again becomes more difficult because one more joint is gone, but weight bearing becomes more single because the ischium, and in fact the entire buttock, can sit firmly in a bucket. Control of the entire extremity is afforded only by motions of the pelvis. Disarticulation of the hip is recommended only in case of necessity. Any thigh stump assures better function than a disarticulation. Whenever possible, sufficient muscle should be preserved to provide a cushion for bearing in an artificial leg. Such amputations can be fitted and many such legs are handled very well. It is especially important to get such an appliance early and to prohibit the postoperative use of crutches in order to avoid the crutch habit.

2. UPPER EXTREMITY

The rule for amputations within the hand is to preserve every bit of every kind of tissue possible for later reconstructive surgery if necessary. This rule, however, should be modified frequently by the consideration of saving function rather than form. There is no point, for instance, in saving individual fingers

which are so badly smashed that they can never be useful. The thumb falls in a different category because of its function in opposing all the fingers, so that even a stiff thumb in the opposed functional position is extremely valuable. Traumatic amputation of the tips of the fingers is well treated by immediate free full thickness skin grafts. In traumatic amputations of finger tips in which the base of the nail bed remains intact it is well to apply narrow adhesive traction strips over the end of the stump; the additional three weeks required to granulate and epithelize the wound is rewarded by a sound and sightly stump. If the entire nail bed is gone it is better to sacrifice enough bone to insure primary closure of adequate soft tissue flaps. In amputation of the middle and ring fingers a good part of the proximal phalanx must be retained in order to prevent lateral deformity of the index and little fingers developing at a later date; if the proximal phalanx cannot be retained, the distal third of the metacarpal should be removed. In loss of the little finger it is well to remove half of the meta-

Sites of election for amputation with expectant function in stump.

carpal in an oblique fashion so as to give a smooth contour to the ulnar side of the hand. In the index finger it is probably better to leave the head of the metacarpal. In the loss of the entire thumb or of all the fingers the situation is not hopeless if function of the remaining digit or digits is retained; either thumb or fingers can be replaced by artificial members against which the remaining movable members can act. The intricate and coordinated movements of the upper extremity cannot be duplicated in artificial limbs. This limitation, for instance, is the basis for disagreement concerning the site of election for amputation about the wrist. For the application of an appliance cosmetically resembling a hand, the forearm should be amputated at the junction of the middle and lower thirds, yet the majority of patients do not wear appliances on the upper extremity and many find the heel of the hand, some movable carpal bones, or even the bulge of the styloid processes useful in movements coordinated with the other hand. In general, it is agreed that as much length as possible is desirable in all amputations in the upper extremity. A terminal scar in the arm or forearm is satisfactory.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

AT THIS YEAR'S COUNCIL MEETING THE REFEREE FOR PREPARATIONS USED NASALLY CALLED ATTENTION TO THE INCREASING NUMBER OF REPORTS OF LIPID PNEUMONIA CAUSED BY THE USE OF OILY PREPARATIONS IN THE NOSE. AS A RESULT OF THE ENSUING DISCUSSION THE COUNCIL ASKED DR. PAUL R. CANNON TO PREPARE A PAPER ON THIS SUBJECT. DR. CANNON KINDLY CONSENTED AND THE COUNCIL ADOPTED THE APPENDED REVIEW FOR PUBLICATION.

PAUL NICHOLAS LEECH, Secretary.

THE PROBLEM OF LIPID PNEUMONIA

A BRIEF REVIEW

PAUL R. CANNON, M.D.
CHICAGO

It is now fifteen years since Laughlen¹ called attention to a type of pneumonia caused by the aspiration into the lungs of oily medicaments administered either intranasally or by mouth. Of the several names which have been applied to the condition, such as lipid pneumonia, lipid pneumonia, fat pneumonia, steatosis of the lungs, pneumonoliposis, lipid cell pneumonia, paraffin pneumonia, oil pneumonia and oil aspiration pneumonia, "lipid pneumonia," suggested recently by Graef,² seems to be the most appropriate. Although many phases of the subject have been clarified³ in the twenty-two or more papers which have been published in this country alone, the fact that so many unsuspected cases continue to be discovered at necropsy suggests that many persons, including physicians, are still unfamiliar with the conditions leading to its development.

The pneumonia varies greatly in severity, depending on the kinds and amounts of lipids aspirated. Some oils are markedly irritating and cause an acute edema and alveolitis with accompanying symptoms of cough and increased respiratory rate. Massive aspirations of oil have led to attacks of choking, cyanosis and suffocation, caused by the accumulation of large amounts of oil

in the alveolar spaces. Particularly serious also is the septic pneumonia which so frequently follows the aspiration of the lipid, owing presumably to the concomitant entrance into the lungs of the irritating oil and pathogenic micro-organisms. This condition is usually accompanied by fever and a persistent cough. In many instances of aspiration of lipids, however, the pulmonary damage is minimal and the symptoms are correspondingly slight or absent. This is particularly true when small amounts of liquid petrolatum enter the lungs. The harmful effects here result from the repeated entrance of the oil into the lungs, its accumulation in the air spaces and its prolonged irritating effect. This form of lipid pneumonia is serious because its development is so insidious. Finally, there are instances of lipid pneumonia in which diagnosis is made only by microscopic examination of the lungs. The demonstration of a few collections of lipophages in alveoli is obviously of little importance in itself; the real value of the observation lies in its proof of the ease with which light oils and fluids can pass from the upper respiratory passages to the lungs. This is perhaps the most important lesson which the study of lipid pneumonia has revealed.

OCCURRENCE AND PATHOGENESIS

Lipid pneumonia may occur whenever exogenous lipids enter the pulmonary tissues and remain there long enough to cause irritation. Its pathogenesis is the most important feature of the subject, because the disease can be prevented only by knowing what types of lipids enter the lungs and under what conditions.

The lipids most commonly concerned are of two main kinds: (1) those taken by mouth and (2) those introduced into the upper respiratory passages. The first group includes cod liver or halibut oil, castor oil, liquid petrolatum or milk fat; the second group comprises the various medicated oils that are used as intranasal sprays or nose drops. Some cases have been reported in which liquid petrolatum was used as a lubricant after tracheotomy or laryngectomy,⁴ and Garvin⁵ has reported an instance in which the patient allowed an oily salve to trickle down the throat daily over a period of about one month. In the cases reported by Davis⁶ and Houck,⁷ medicated liquid petrolatum was instilled directly into the trachea, and in one case the oil was used as a nasal douche, three or four times a day, over a period of nine years. It was estimated that during this time the patient had used more than 9 gallons of liquid petrolatum!

The earlier reports on the occurrence of lipid pneumonia led to the belief that it is essentially a disease of infants and children. Accumulated evidence has proved, however, that it affects all ages, and at least 105 cases, most of which were discovered at necropsy, have been reported in adults.⁸ The view, furthermore, that it occurs almost entirely in weakened individuals and particularly in those with defects of deglutition is no longer correct; it is now certain that healthy persons may develop severe types of lipid pneumonia, especially

if they use medicated liquid petrolatum intranasally in large quantities over long periods of time.

Aspiration of milk fat, fish oil or liquid petrolatum may occur under conditions which are difficult or at times impossible to control, as, for instance, in babies or debilitated adults who are recumbent for long periods of time. Aspiration of these lipids is further favored by conditions which interfere with normal processes of deglutition, such as cleft palate, convulsions, spasms, frequent attacks of gagging or vomiting, cerebral birth injuries and congenital neurologic disorders. Similarly, in adults who use liquid petrolatum for the relief of constipation, pulmonary aspiration may be favored by dysphagia caused by nervous disorders, cerebral hemorrhage, brain tumors, or by local inflammations or neoplasms of the mouth, throat, larynx or esophagus.

Of particular interest, because it is more easily controlled, is the type associated with the intranasal use of medicated liquid petrolatum. This form of therapy is widespread, not only in medical practice, but also in home medication. Although physicians are beginning to discourage the custom, many persons continue to use the "nasal oils" because of the extensive advertising campaigns of the makers. One company, over the radio, urges every one with symptoms of a beginning cold to put "a few drops in each nostril" when needed. No warning is given as to the possible harm resulting from their excessive or habitual use. Abandonment of this type of medication will be slow because of the fact that so many persons have used oily nose drops with no apparent ill effects. This, however, no more indicates the harmlessness of the practice than does the occasional ingestion of small amounts of lead prove that it is not a poison and can therefore be eaten repeatedly over a long period.

It is particularly regrettable that liquid petrolatum was selected as the solvent for various medicaments in the treatment of infections of the upper respiratory tract. This oil was chosen mainly because of the belief that it is "bland," is nonirritating, does not become rancid, spreads easily, and prevents drying and crusting of the respiratory surfaces. It was not realized how readily the oil, under certain conditions, can enter the lungs and that the persistent use of a few drops a day over a period of days and weeks can lead to the entrance of considerable quantities. Walsh and Cannon⁹ have cited the directions given by one manufacturer that "for children from six months to ten years of age the dosage is one-half dropperful in each nostril three or four times a day." As this dropper contained 1.5 cc., a six months old child would receive a total dose of from 4.5 to 6 cc. a day, or more than an ounce a week. If only a third of this got into the small lungs of a baby, a large area of pulmonary tissue would necessarily be affected. The most unfortunate aspect of the problem, however, is the fact that liquid petrolatum cannot be metabolized by tissue enzymes as can some of the animal and vegetable oils and hence remains as a foreign body irritant. This effect in subcutaneous tissues is well known as the so-called paraffinoma. Its similar effect in the pulmonary tissues caused Ikeda¹⁰ to designate this type of lipid pneumonia "paraffinoma of the lung."

MODE OF ENTRANCE INTO THE LUNGS

Liquid petrolatum, either when instilled or when sprayed into the nostrils, may enter the lungs in varying amounts, depending on the dosage, the frequency with

which it is applied and the extent to which the epiglottis functions effectively. It reaches the lungs fairly easily, however, because, being light, it does not elicit the cough reflex but enters the glottis and is aspirated or allowed to gravitate into the alveolar spaces. This is especially likely to happen during sleep if the oil has been used before retiring, as shown by the demonstration by Quinn and Meyer¹¹ that iodized poppy-seed oil instilled into a patient's nose during sleep could be readily demonstrated in the bronchial tree. Although probably only a small proportion of the oil enters the lungs, the remainder being swallowed, long-continued use may lead, eventually, to its accumulation in considerable quantities, because, once within the alveolar spaces, comparatively little resorption apparently occurs. This fact is strikingly shown in the case reported by Fischer-Wasels¹² of a 70 year old woman who was thought to have a tumor of the lungs. At necropsy, however, it was discovered that the supposedly neoplastic masses contained large quantities of a non-saponifiable oil. Inquiry revealed that this woman, for many years, had had the daily habit of spraying her nasal passages with large amounts of a mentholated liquid petrolatum. Similar cases have since been reported.¹³ Fischer-Wasels suggested that the menthol in these preparations may act as a mild local anesthetic and thus lessen the tendency for the cough or gag reflex to prevent the entrance of the oil into the trachea.

PATHOLOGIC EFFECTS IN THE LUNGS

The effects of this entrance of foreign lipids may be acute or chronic, localized or diffuse. The oils are all irritating, although in varying degree, and may cause inflammatory changes ranging from simple congestion and edema to necrosis. Pinkerton¹⁴ demonstrated quite clearly that the animal oils, particularly cod liver oil, are highly irritating, whereas some of the vegetable oils, such as olive oil, cottonseed oil, sesame oil and poppy-seed oil, are relatively nontoxic. This blandness of vegetable oils is of practical importance in that iodized poppy-seed oil has been so useful in bronchography and has apparently led to no serious after-effects in the lungs.¹⁵ Pinkerton suggested that the greater tissue-damaging effect of the animal oils may be due to their greater hydrolytic cleavage into irritating fatty acids. He observed, however, that chaulmoogra oil is markedly toxic to pulmonary tissues, and Graef² has recently pointed out that several of the vegetable oils, notably croton oil, castor oil and peanut oil, are exceedingly active tissue irritants. There is no doubt, however, that cod liver oil is extremely injurious to pulmonary tissues and its aspiration has been followed by severe cases of lipid pneumonia, some even with abscess formation.¹⁶

Liquid petrolatum, although less acutely damaging than the aforementioned oils, is far from bland. Experiments performed by Cannon and Walsh¹⁷ showed that

the intranasal instillation of purified liquid petrolatum into healthy rabbits caused the development of acute pulmonary edema, proving that the oil in the lungs can injure capillaries sufficiently to cause increased capillary permeability and the leakage of albumin into the alveolar spaces. This fact has a definite bearing on the intranasal use of medicated liquid petrolatum in infants and young children with acute infections of the upper part of the respiratory tract. Under these conditions it is probable that whatever oil enters the lungs carries with it bacteria or viruses, and these, because of the edema induced by the oil, may find conditions more favorable for development, thus initiating a bronchopneumonia. In case of death all evidence of the early injurious effects of the oil in setting the stage for the terminal pneumonia might easily be obscured by the abundant inflammatory exudate.

The chronic effects in the lungs from the aspiration of liquid petrolatum are particularly severe, owing to the fact that it leads to the development of reticulum fibers, giant cells and, in time, abundant fibrosis. The subsequent formation of scar tissue is, consequently, as destructive to pulmonary integrity as is any other fibrosing process. It is likely, furthermore, to be more insidious, because the resultant persistent cough may lead to the more frequent use of nasal sprays or instillations in a further attempt to alleviate the cough.

Although the effects from the aspiration of oils are confined for the most part to the lungs and tracheo-bronchial lymph nodes, instances of blood stream dissemination are recorded¹⁸ in which liquid petrolatum has been found as encapsulated masses of oil giving the appearance of tubercle-like lesions in the spleen and liver. In the case reported by Young, Applebaum and Wasserman¹⁹ in which cod liver oil had been aspirated, renal lesions suggestive of periarteritis and diffuse glomerular nephritis were attributed to embolic blockage by oil droplets.

Microscopic demonstration of the presence of oily materials is usually simple although the differentiation of the kinds, and the determination whether they are endogenous or exogenous, is more difficult. With exogenous lipids the alveolar spaces are filled characteristically with large vacuolated mononuclear cells which at times have almost a signet-ring appearance. These so-called lipophages fill many air spaces and may at times be coughed up and identified in smears of the sputum. Liquid petrolatum can be partially identified by the fact that it stains with scarlet red but does not reduce osmic acid. It is also insoluble in absolute alcohol. Cod liver oil, on the other hand, reduces osmic acid and, as emphasized particularly by Pinkerton, forms characteristic acid-fast membranes at the edges of the oil masses which can be demonstrated by the Ziehl-Neelsen method. More complete and accurate identification of the oils is best made by chemical extraction of tissues, with subsequent determination of boiling points, iodine number, degree of saponification, acrolein reaction and specific color reactions. By these methods Pinkerton, Graef and Freiman, Engelberg and Merrit, particularly, have clarified several important details of the general problem. Similar chemical studies will add much valuable information concerning pathogenesis of lipid pneumonia in individual cases.

DIAGNOSIS

The diagnosis of lipid pneumonia, although usually not made ante mortem except in the severer cases, is possible at times. Of first importance is the history of the use of oily materials by mouth or in the nasal passages, with information as to amounts, duration and frequency of use. A persistent cough may be present, and in some instances there has been a history of choking attacks. Periods of low grade fever, due presumably to an accompanying septic pneumonia, have been observed. These symptoms, in conjunction with the physical observation of impaired pulmonary resonance and altered breath sounds, are informative, particularly if observed in a weak, debilitated or premature infant and in infants or adults with dysphagia from any cause.

Laboratory aids to diagnosis include the demonstration of oil laden macrophages in coughed up sputum or in tissue obtained by the bronchoscope for biopsy. Roentgenologists²⁰ have added considerably to the means of diagnosis by their demonstration of areas of increased density in the posterior, dependent portions of the lungs and in the perihilar regions with a tendency to be more marked on the right side. It is obvious, however, that these effects are evident mainly in patients with extensive and chronic involvement. Roentgenologists also emphasize the necessity for serial roentgenograms, particularly in the moderate and mild cases.

The chronic form of lipid pneumonia, especially that due to liquid petrolatum, must be differentiated from such conditions as pneumoconiosis, chronic bronchitis or bronchiectasis, chronic asthma, passive congestion, unresolved pneumonia, chronic fibroid tuberculosis, fungous infections of the lungs and bronchogenic carcinoma. Accurate differentiation is especially important with respect to the latter condition because of the increasing employment of surgery in its treatment. Errors in diagnosis here are particularly serious and, indeed, have already occurred. Rigler²¹ reported a case of unilateral lipid pneumonia in an adult which was diagnosed as bronchogenic carcinoma, and in the case reported by Thomas and Rienhoff²² pneumonectomy was performed on a 35 year old man on whom a diagnosis of carcinoma of the lung had been made. Death occurred from infection a few days later and the necropsy revealed a localized lipid pneumonia of the middle lobe of the right lung. It was learned later that "for over three years it had been the habit of the patient to apply medicated nasal spray with an atomizer, especially at night before retiring. The spray consisted of liquid petrolatum containing menthol and ephedrine." As so many adults are using oily nose drops and sprays by self medication, thoracic surgeons will need to give serious attention to the possible presence of chronic lipid pneumonia in the differential diagnosis of carcinoma of the lung.

INCIDENCE

It is impossible at present to ascertain the incidence of lipid pneumonia, and only certain inferences can be drawn from the evidence now available. The clinical effects vary greatly because of the different types and amounts of oils aspirated and, except in the severer cases, clinical diagnosis is therefore difficult. Most of the cases reported have been diagnosed at necropsy;

20. Pierson, J. W.: Some Unusual Pneumonias Associated with Aspiration of Fats and Oil in Lungs, *Am. J. Roentgenol.* **27**: 572-579 (April) 1932. Brown, R. S., and Wolman, I. J.: Lipoid Pneumonia in Infants and Children, *Radiology* **32**: 1-7 (Jan.) 1939. Davis.²

there are, no doubt, many more that have been overlooked or left unreported by pathologists. It is obvious that postmortem evidence alone can tell but little about the incidence of many kinds of disease. This is important to bear in mind because many physicians feel that, as so few necropsy cases have been reported, lipid pneumonia is a rare disease. By such logic, however, one would have to conclude that many diseases are rare, as for example morphinism, vitamin B deficiency or allergy. As the mild cases of lipid pneumonia are usually unsuspected, it is probably a more common malady than the nearly 200 cases which have been reported would indicate.

Furthermore, the incidence of lipid aspiration will vary directly with the extent to which pathologists make systematic routine histopathologic examinations of the lungs in every necropsy. Pinkerton²³ found 6 instances in 290 consecutive necropsies of infants and young children; Ikeda²⁴ found 7 in 101 consecutive necropsies. Freiman, Engelberg and Merrit,⁸ in attempting to ascertain the incidence among elderly patients with chronic disease, found 41 instances in 3,500 consecutive necropsies. We have found 39 instances in 2,000 consecutive necropsies, of which 12 were of infants and children and 27 of adults. These figures give a rough idea of the extent to which lipids may be aspirated, but it is obvious that the incidence of this aspiration must vary widely in different parts of the country and of the world, depending on the distribution of respiratory infections and the tendency of physicians and of the public to use medicinal oils.

PREVENTION

Lipid pneumonia, being essentially a man-made disease, can be prevented largely by the extent to which the conditions now known to favor its development are eliminated. In infants greater care can be paid to methods of administering fish oil and liquid petrolatum in order to avoid the hazards of aspiration, as for instance by the giving of smaller amounts per dose or by using concentrates. One of the great hazards can be removed by the elimination of all forcible feeding of cod liver oil or liquid petrolatum. The disastrous consequences of this practice have already been mentioned. Monfort²⁵ cites a case in which a 7 weeks old child in good health was forcibly given liquid petrolatum while crying. Soon after, the child developed a hacking cough, rapid respiration (86-88 per minute) with periods of apnea and with normal temperature and blood count. Roentgenograms revealed extensive bilateral infiltration in the hilar spaces. Eleven days later death resulted from bronchopneumonia. Greater care can also be given to the feeding of prematurely born or to weakened or debilitated infants.²⁶ Pinkerton warned against the practice of feeding such infants while lying on their backs, and Monfort has called attention to the need for abandoning the not uncommon practice of propping the nursing bottle on a pillow with the nipple remaining in the mouth. It is probable, therefore, that some cases of lipid aspiration can be prevented by giving more attention to these and other causative factors such as the feeding of comatose individuals, the use of gavage and the prevention and control of vomiting.

The problem of prevention of lipid pneumonia due to intranasal medication is more hopeful. Of the cases in

adults thus far reported in the literature, approximately 20 per cent were acquired because of intranasal medication, and in a series of cases including infants, children and adults, reviewed by Walsh and Cannon, approximately a third resulted from intranasal medication. It would seem advisable, therefore, to reexamine the rationale of local medication of the upper part of the respiratory tract in order to ascertain whether the benefits which may result from this mode of therapy outweigh the harmful effects now so well demonstrated in the massive natural experiment of lipid pneumonia.

Healy,²⁷ in discussing recently the problem of therapy in acute rhinitis, said "The ideal therapeutic aims of local medication in acute rhinitis are the reduction of nasal congestion, the promotion or restoration of ciliary function and the destruction of pathogenic organisms." He cited evidence from the work of Proetz,²⁸ Lierle and Moore²⁹ and Fenton and Larsell³⁰ that many of the commonly used nasal oils and so-called antiseptics actually impair or paralyze ciliary activity and even destroy respiratory epithelium. Walsh and I⁹ have discussed elsewhere the general problem of intranasal medication and have challenged the assumption that the solution of medicaments in liquid petrolatum possesses any advantage over aqueous solutions containing dextrose or sodium chloride. We have also questioned the generally held opinion that such antiseptics as menthol, eucalyptol, guaiacol or iodine, when dissolved in oil or in any other solute, can exert any important bactericidal action on bacteria or viruses developing in or beneath the nasal mucosa. Scientific proof, not personal opinion of the physician or patient, is necessary before we can rightly conclude that any of these exert a genuinely effective antibacterial or antiviral action. If only symptomatic anticongestive effects are aimed at by local medication, these can be as well secured by the use of aqueous solutions, thus avoiding the real dangers associated with the use of irritating oils. Statements that these intranasal preparations exert a "stimulating," "healing" or "bactericidal" effect should not be accepted until there is some objective evidence as to their validity. At present there is considerable evidence to the contrary. As Proetz³¹ has recently said in stressing the importance of the functional point of view in rhinology and the need for reexamination of therapeutic methods empirically employed, "It is likewise progress, though it seldom occurs to us to abandon old methods . . . when they have been discredited. Not to abandon them after they have been proved harmful is reprehensible."

No argument is necessary regarding the need for additional information about the therapy of infections of the upper part of the respiratory tract. Too much trust, however, has hitherto been placed on empiric treatment rather than controlled observation. As a result, the public has accepted this attitude, and self medication with nasal oils is widespread. It is not likely that this will be stopped until the medical profession takes the leadership in the educational campaign to eliminate the practice.

SATURDAY, DECEMBER 21, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

VIRUS STUDIES IN A NEW RESPIRATORY INFECTION

Many reports have appeared recently concerning an acute infectious disease of the respiratory tract in man, associated with unusual pathologic changes in the lungs. Sporadic cases as well as minor epidemics have been described occurring in various parts of the United States and abroad (England, France, Hawaii, Spain). The disease has been described under a variety of names, such as acute influenza pneumonitis (Bowen), acute pneumonitis (Allen), atypical pneumonia (Cass), acute interstitial pneumonitis (Smiley and others), bronchopneumonia (Miller and Hayes), atypical bronchopneumonia (Murray), circumscribed pneumonia and disseminated focal pneumonia. All these terms are too restrictive, since they describe pulmonary changes observed only in the more severe cases. The majority of the cases do not present these changes. Furthermore,

the terms fail to throw any light on the etiology of the infection. The disease differs from the familiar forms of lobar pneumonia caused by pneumococci and from bronchopneumonia caused by the hemolytic streptococcus, staphylococcus, *Pasteurella tularensis* and the forms accompanying acute infectious diseases of infancy and childhood.

Reimann¹ in 1938 described a series of 8 cases of an unusual, uniform, severe infection of the respiratory tract. The disease occurred in adults and began as a mild infection. This was followed by severe, diffuse atypical pneumonia and in the 2 fatal cases by symptoms of encephalitis. Dyspnea, cyanosis, cough without sputum, drowsiness and profuse sweating were the chief characteristics. Blood cultures remained sterile, and agglutinins for other bacillary diseases were absent. Kneeland and Smetana² reported 52 cases of atypical bronchopneumonia observed within the past two years at the Presbyterian Hospital, New York. The course of the infection was characterized by an insidious onset, a normal or only slightly elevated leukocyte count early in the disease, a sputum entirely comparable from a bacteriologic standpoint to that of healthy persons. The pulmonary consolidation was incomplete and tended to be migratory. Most of the cases were mild. The more severe cases presented a prolonged course, a tendency to relapse, cyanosis with obstructed breathing and leukocytosis late in the disease. Sulfapyridine had no antipyretic effect nor any effect on the course of the disease. The microscopic features of the pneumonia in the 1 fatal case were likewise unusual and were characterized by a mononuclear cell exudate and an acute pulmonary vasculitis.

There is abundant evidence to show that the disease is readily transmissible. Most of the reports refer to the occurrence of the disease among college students or in garrisoned troops. Miller and Hayes³ reported a small epidemic at the University of Oregon. Smiley, Showacre, Lee and Ferris⁴ reported a series of 86 cases occurring in a fifteen month period among the students at the Cornell University, while Maxfield⁵ reported a similar epidemic involving 63 cases of "atypical leukopenia pneumonia" seen at the Baylor Hospital, Dallas, Texas. Longcope⁶ points out that more than half of the 32 cases of this particular variety of pulmonary disease observed by him at the Johns Hopkins Hospital occurred during October, November and December, whereas pneumococcal pneumonia is most prevalent in Baltimore from December to May, a period

during which only 8 of his 32 cases were encountered. The onset of the disease was similar in most of the cases, but the subsequent course varied greatly from a mild infection to one which was extremely grave or fatal. There was a moderate leukopenia in the beginning, the leukocytes rising in the later stage, seldom, however, higher than 13,000 and without a corresponding increase in the polymorphonuclear neutrophilic leukocytes. Frequently repeated blood cultures were negative, as were agglutinin reactions for *Pasteurella tularensis*, *Brucella abortus* and *Salmonella suipestifer*. Among the features which distinguish this infection as a disease entity Longcope points out the onset with high fever, headache, sweating, rasping, nonproductive cough that may become paroxysmal, the meager physical signs of consolidation of the lungs with spotty or dense shadows in the roentgenograms, the normal or slightly elevated leukocyte count and the infrequency of chill, pain in the chest and rusty sputum. The persistence of signs and symptoms for seven to fourteen days even in the mild cases and the prolonged course lasting three weeks or more in the severest infections form a striking feature. The disease presents many features which in Longcope's opinion suggest that it might be caused by a filtrable virus. These are its contagiousness, the long incubation period, the inability to demonstrate by culture of the sputum or of blood or by agglutination reactions that it is associated with any known pathogenic bacteria, and, finally, the peculiarity of the pathologic changes consisting of a mononuclear cell exudate into the pulmonary alveoli. Reimann and Havens⁷ describe an outbreak of an epidemic disease of the respiratory tract which occurred in Philadelphia in 1939. Of a group of 813 persons in the personnel of the Jefferson Medical College and Hospital 50 per cent were ill. Eighty-eight per cent of the patients were ill with nasopharyngolaryngitis, 6 per cent had tracheobronchitis and 6 per cent had tracheobronchopneumonia. The disease resembled epidemic influenza in many respects but was caused by a different agent. These authors call attention to the fact that, from the standpoint of public health, mild infections are all potentially dangerous. They may be the precursors of an outbreak of a more serious disease of the respiratory tract caused by the invasion of bacteria like that which occurred in 1918-1919 after influenza. Reimann believes that the failure to isolate a virus of these cases was probably due to the delay before attempts were made or to the weak pathogenicity of the virus for the species of animals which were inoculated. With only 2 patients of his first series¹ attempts were made to obtain a virus as early as the fourth day of illness. From both patients Dr. Stokes⁸ and Dr. Francis obtained an unusual virus from the nasopharyngeal washings of one and from the blood

of the other. It was equally virulent for mice and caused pneumonia and encephalitis about two weeks after inoculation. Unfortunately, however, the agent was lost before serologic tests could be done. Consequently evidence was not obtained regarding any etiologic relationship. Now Weir and Horsfall⁹ report unsuccessful attempts to infect a variety of animals such as ferrets, mice, guinea pigs, rabbits, monkeys, opossums, skunks, woodchucks, voles, deer mice and Syrian hamsters by intranasal inoculation with throat washings from a number of clinically typical cases. They took the infectious material to Kingston, Jamaica, in order to attempt to transmit the infection to the wild mongoose. The abundance of this animal in some of the Caribbean islands and the resemblance to the ferret were the chief reasons for this choice. They have succeeded in recovering a virus capable of producing pulmonary consolidation in this animal. The virus was filtrable through Berkefeld V and N candles, was not inactivated by glycerin or by freezing and drying in vacuum, and was propagated for at least thirty serial passages on the chorio-allantoic membrane of the developing chick embryo. Normal mongooses placed in contact with infected mongooses developed pulmonary consolidation. The virus was neutralized by the serum of mongooses convalescent from the infection but was not neutralized by normal mongoose serum. Serum of human beings convalescent from acute pneumonitis also neutralizes the virus, but serum obtained from the same persons during the acute phase of the disease failed to do so. The authors state that this virus is the cause of acute pneumonitis in human beings.

PULMONARY EMBOLISM IN MEDICAL PATIENTS

In the practice of surgery, pulmonary embolism has long been recognized as a frequent and important complication. Strangely, in the practice of internal medicine and in general medical practice this condition has been long neglected. Dr. Paul Dudley White,¹ of Boston, has recently reviewed twenty years of personal experience with pulmonary embolism and heart disease. The frequency of failure to recognize pulmonary embolism stresses the importance of the condition in simulating or complicating heart disease. From 1930 to 1940 he made the diagnosis of pulmonary embolism in his own practice seven times more often than in the ten year period from 1920 to 1930, though there was no essential difference either in the type of practice or in the numbers of new and old patients seen. As a matter of fact, even in the second decade the condition was largely overlooked during the first half; two thirds of the cases were seen during the last three of the total twenty

years. Confirmation of the diagnosis was established by undoubted clinical or necroscopic evidence. Analysis of this experience and of the postmortem reports at the Massachusetts General Hospital indicates that there has not been an abrupt increase in pulmonary embolism and infarction but that the major part at least of the supposed increase was due to greater search for and better recognition of the condition. Erroneous clinical diagnoses of bronchial or atypical lobar pneumonia, of congestive heart failure (with pulmonary edema), and even of coronary thrombosis (in a few cases) have been responsible for some of the errors of omission.

Pulmonary embolism may simulate heart disease (coronary thrombosis or congestive failure) but more often it complicates heart disease, especially mitral stenosis or congestive heart failure from any cause. Peripheral venous thrombosis is clinically evident in a minority of the cases and even concealed at necropsy in many cases unless the veins are actually explored. In some 70 per cent of the medical cases with pulmonary embolism and infarction seen post mortem, venous thrombosis, which gave little or no clinical evidence of its presence, was present in the deep veins of the legs. Sixty per cent of all cases of pulmonary embolism and infarction are in "medical" patients (half with heart disease and half without).² Of course, in many a case the large dilated heart allows an intracardiac thrombus in the right heart chambers to be the source of pulmonary embolism, but this actually seems to be a relatively uncommon site of origin.

Clues to the diagnosis of obscure pulmonary embolism are presented by White as follows: (1) the occurrence of unexplained fever, leukocytosis, tachycardia, faintness, prostration, dyspnea, asthma or even jaundice (from hemolysis of a large infarct plus an engorged liver), especially in a patient with heart disease (and particularly in the presence of mitral stenosis or heart failure); (2) the finding of lung signs (rales or consolidation) not adequately explained by either congestive heart failure or pulmonary infection; (3) the periodic recurrence at short intervals of episodes that individually might be mistaken for acute coronary occlusion but which in series are much more likely to mean repeated pulmonary embolism; (4) the inexplicable lack of response of a case of congestive heart failure to therapy which seemingly should be adequate (ruling out other factors such as infection, infarction elsewhere than in the lungs and thyrotoxicosis), and (5) in a few cases the characteristic electrocardiogram of the acute cor pulmonale (prominent S waves in lead 1, low, flat or even inverted T waves in lead 2, prominent Q waves and inverted T waves in lead 3 and low, flat or inverted T waves in lead 4) when the right ventricle is dilated by massive embolism (not therefore in the

majority of cases of pulmonary embolism) and simulating at first glance the electrocardiogram of acute coronary thrombosis with basal infarction.

Pulmonary embolism always demands a careful search for peripheral venous thrombosis and heart disease. Its detection explains obscure signs and symptoms, refractoriness to treatment and periodic episodes of fever, tachycardia or collapse. Its presence reveals the folly of forcing unnecessarily vigorous, perhaps toxic, therapy for congestive heart failure and points to the possible help, even life saving in rare cases, to be derived from ligation of a peripheral vein.

The chief lesson to be learned from studies of important diagnostic errors of omission is the necessity to remember all the possible common causes of any given combination of symptoms and signs. Pulmonary embolism is a common cause of primary or complicating intrathoracic disease.

Current Comment

MONGOLIAN SPOTS AND NEGRO HEREDITY

In a recent discussion¹ of a case involving rape the question of Mongolian spots as an indication of Negro inheritance received special attention. The so-called Mongolian spot is a curious manifestation of pigmentation which consists of one or more bluish dark spots that appear at birth in the sacral, lumbar and gluteal regions. These spots resemble the black and blue marks on the skin after a contusion, and, according to Dr. Carleton Simon, consulting criminologist to the Association of Chiefs of Police of the State of New York, one of the consultants in the case in question, they are more distinct the first two weeks, becoming fainter and disappearing in from two months to two years. Ninety per cent of all Japanese infants have them, and they are common also among infants of the Javanese, Malays, Chinese, natives of Greenland and tribes of the American Indian. In the Negro the Mongolian spot is rarely absent, several of the spots usually being present in the same individual. They have also been found in a few instances among Russians and the darker Mediterranean white races. Dr. Hooton, writing on the same subject, points out that the presence of Mongoloid spots is suggestive but not definitive of Negro blood and occurs also in infancy in many of the darker pigmented races. Parallel discussions of other features which have been considered as indicative of Negro blood, including physical characteristics such as increased pigment in the eyes and nails and blood tests, lead to the conclusion that there is as yet no known scientific test that will identify the racial background of a person whose blood contains so many and so dilute racial strains as to make his racial origins doubtful. Furthermore, the mathematical computation that in twenty generations every individual is the lineal descendant of

more than a million forebears symbolizes the complicated nature of the subject. In any event, the presence of Mongolian spots alone cannot be considered to prove the presence of Negro blood in any immediate sense.

OIL ASPIRATION PNEUMONIA

Oil pneumonia, known also as lipid or lipoid pneumonia, in adults, due to liquid petrolatum, has been occurring increasingly in recent years. Errors in diagnosis may occur whereby the condition is overlooked, so that it is detected only at necropsy, if at all. Freiman and his associates¹ have shown that the aspiration of liquid petrolatum is facilitated by the fact that it is a bland drug, nonirritant to the pharyngeal mucosa and exciting no reflex inhibition. When once aspirated, gravity and inspiratory suction seem to control its disposition in the lungs. This is indicated by the fact that the lower right and left lobes are preponderantly affected. Forty-seven mostly debilitated recumbent and dysphagic patients who were suffering from some incurable disease such as carcinoma or arteriosclerosis, with an average age level of 61.8 years, had habitually used liquid petrolatum in relatively large quantities. Forty-one of these were studied at necropsy. The microscopic examination of pulmonary tissue indicates two stages in the evolution of the disease, a prompt macrophagic reaction followed by a slower process of fibrous proliferation of interstitial tissue, which eventually prevails. As fibrosis increases, cellularity diminishes. Finally there remains only a mass of hyalinized fibrous tissue with entrapped oil, a true paraffinoma. The difficulty of clinical diagnosis is increased by the absence of specific symptoms and signs. Symptoms such as cough, blood-streaked sputum, if present, pain in the chest and intercurrent fever are those associated with other forms of chronic pulmonitis. Malignant growths present elsewhere than in the lung may lead to a wrong interpretation of pulmonary shadows as metastatic in origin; but here the failure of pulmonary infiltration to increase in size over a period of months after cessation of intake of oil is strong evidence against tumoral metastasis. Laboratory data are only occasionally helpful, as the leukocyte count and the erythrocyte sedimentation rate are not affected by liquid petrolatum by itself. On the other hand, the presence in the sputum of oil globules is diagnostically valuable, if liquid petrolatum can be identified chemically or by differential staining. However, diagnosis is significantly aided by roentgenoscopy. In the early stages the markings in the lower lung fields are exaggerated. As the lesions progress, linear and nodular infiltrations develop until finally areas of consolidation are formed which are always situated at one or both pulmonary bases and which lie close to the cardiac shadow that extends from the hilus to the diaphragm. Serial roentgenograms may show no change for years other than progressive fibrosis, yet the persistence of pulmonary shadows in a patient with dysphagia receiving liquid

petrolatum justifies the diagnosis of oil aspiration pneumonia. The essential features of oil pneumonia are dysphagia, a long history of intake of oil, roentgenographic demonstration of persistent, unchanging consolidations characteristically situated in the mesial portions of the bases of both lungs and complete absence of clinical evidence of pulmonary disease; but they are rarely all present. The difficulty of correct diagnosis may be illustrated by a case cited from the authors' own experience in which oil pneumonia developed during two and one-half years of hospitalization of a patient suffering with degenerative cerebellar disease, pseudobulbar palsy and dysphagia. The progress of the lesion was followed roentgenologically throughout the illness and yet the diagnosis was not established until it was too late to affect the outcome by the withdrawal of the oil. The presence of persistent pulmonary consolidations with disproportionately slight symptoms or of infiltrations which do not fit into any well established disease pattern should suggest oil pneumonia. The authors do not consider oil aspiration pneumonia a direct cause of death, unless in some extreme case, as one which fell within their experience, in which the pulmonary lesion was so extensive as to induce asphyxia. Usually the patient lives for an indefinite time and finally succumbs to his primary disease or to a secondary infection. However, purulent bronchiolitis and bronchitis, bronchiolectasis, occasionally bronchiectasis and recurring episodes of bronchopneumonia may be concomitant conditions over a considerable period. Though the use of liquid petrolatum is not necessarily productive of oil pneumonia even in the presence of some predisposing factor, it is not without potential danger. Its promiscuous use, especially by enfeebled or dysphagic persons, should be discouraged.

BODY WEIGHT AND CANCER INCIDENCE

Many external factors affect the incidence of cancer. Among those recently discussed are climate, exposure to the elements, especially sunlight, and geographic location.¹ Now Tannenbaum² presents experimental and statistical evidence on the relation of body weight to the development of cancer. In both animals and man individuals of average or less than average weight are not as likely to develop cancer as those who are overweight, he believes. This tentative conclusion requires careful checking, and the establishment and maintenance of weight levels with a view to the prevention of human cancer can as yet be considered only as an experimental procedure. In the light of the curiously large number of correlations between cancer and internal and external factors which are now receiving attention, it is necessary to weigh all the evidence carefully and not to accept the suggestions as established until unequivocal proof has been presented.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

CHANGES IN COMMITTEE CHAIRMANSHIPS OF DIVISION OF MEDICAL SCIENCES OF NATIONAL RESEARCH COUNCIL

In order to meet new and expanding requirements in the field of medical preparedness, the following changes in the chairmanships and organization of committees in the Division of Medical Sciences of the National Research Council have been announced by Dr. Lewis H. Weed, chairman of the Division of Medical Sciences:

Russell M. Wilder, Rochester, Minn., resigns as chairman of the Committee on Medicine (remains member of committee) to become chairman of the Committee on Food and Nutrition of the Division of Biology and Agriculture and of the Division of Medical Sciences.

O. H. Perry Pepper, Philadelphia, becomes chairman of the Committee on Medicine, resigned as chairman of the Subcommittee on Diagnosis and Therapeutics.

Hugh Morgan, Nashville, Tenn., becomes vice chairman of the Committee on Medicine.

James McLester, Birmingham, Ala., becomes chairman of the Subcommittee on Medical Nutrition.

Warfield T. Longcope, Baltimore, becomes chairman of the Subcommittee on Diagnosis and Therapeutics.

Henry Meleney, Nashville, Tenn., becomes chairman of the Subcommittee on Tropical Diseases vice Wilbur A. Sawyer (resigning because of duties abroad).

The complete organization was described in THE JOURNAL, November 9, page 1640.

A COMMITTEE ON FOOD AND NUTRITION TO ADVISE GOVERNMENT

The National Research Council announces the appointment of a Committee on Food and Nutrition to advise the federal government on nutritional aspects of national defense. This committee, appointed at the request of Miss Harriet Elliott, head of the Consumer Division of the National Defense Advisory Commission, will concern itself with improving the nutrition of the general population. A separate National Research Council subcommittee is already advising the Army and Navy on nutrition for these services. Several members of this subcommittee are also members of the new Committee on Food and Nutrition.

Dr. Russell M. Wilder, of the Mayo Clinic, Rochester, Minn., is chairman of the new committee. Serving with him as advisers to the government in planning its program of national nutrition for defense are specialists from agriculture, industry and science dealing with food and nutrition.

Representing the food processing industry are Mr. Cullen Thomas, executive of General Mills Corporation, Minneapolis, and Dr. Samuel C. Prescott, dean of science, Massachusetts Institute of Technology, and member of the Institute of Food Technologists. For advice on problems of food production and distribution the committee includes Dr. John N. Black, professor

of agricultural economics at Harvard University. Dr. F. G. Boudreau, now executive director of the Milbank Memorial Fund but formerly head of the League of Nations technical committee on nutrition, and Dr. Joseph S. Davis, professor of economic research and director of the Food Research Institute, Stanford University, will contribute their knowledge of world food problems, as will Dr. John B. Youmans, associate professor of medicine, Vanderbilt University, who is now studying the food problems of both occupied and unoccupied France for the Rockefeller Foundation.

Advice on translating nutritional science into menus and diet lists for the welfare of the family will come to the housewife from such experts as Dr. Icie Macy Hoobler, director of research laboratory, Children's Fund of Michigan, Detroit; Dr. Helen S. Mitchell, research professor of nutrition, Massachusetts State College, Amherst, and Dr. Lydia J. Roberts, chairman of the Department of Home Economics, University of Chicago.

Specialists in certain phases of nutrition are serving on the committee. In the vitamin field a group is made up of Dr. R. R. Williams, chemical director, Bell Telephone Laboratories, who first isolated and later synthesized thiamine; Dr. George R. Cowgill, associate professor of physiologic chemistry, Yale University; Dr. C. A. Elvehjem, professor of agricultural chemistry, University of Wisconsin, and Dr. Norman Jolliffe, associate professor of medicine, New York University School of Medicine; Dr. Henry Borsook, professor of biochemistry, California Institute of Technology; Dr. Charles Glenn King, professor of chemistry, University of Pittsburgh, known for his isolation in pure form of vitamin C; Dr. Philip C. Jeans, professor of pediatrics, State University of Iowa, and Dr. W. C. Rose, professor of biochemistry, University of Illinois.

Broad as well as specialized knowledge of nutritional science will be contributed by Dr. James McLester, professor of medicine, University of Alabama, and Dr. L. A. Maynard, professor of animal nutrition and director, U. S. Plant, Soil and Nutrition Laboratory, Cornell University. Dr. McLester is chairman of the American Medical Association's Council on Foods and Nutrition and Dr. Maynard is secretary of the American Institute of Nutrition.

The committee recently held its first meeting in Washington. It gave consideration to the improvement of white flour, which is well known to be deficient in the B vitamins, necessary for health and morale, and in minerals. It will consider the possibilities of improving the quality of sugar, which likewise has been deprived of the vitamins and minerals contained in the material from which it is made—sugar cane and beets. Means will also be sought for improving the nutritional qualities of other staple foods, such as the edible fats.

It is the quality of the nation's food that is important in the present emergency, it was pointed out, whereas in the war of 1914-1918 the quantity of food was the

chief concern. It is for this reason that Miss Elliott asked for a committee of scientists to advise her, through Dr. M. L. Wilson, director of extension work, U. S. Department of Agriculture, how much of each important nutritional factor should be included in the national diet, and what things the public should be taught to eat. A national program of nutritional education is in planning, directed by Dr. Wilson.

One of the things to be taught, the committee decided at its first meeting, is that there is no detectable difference between the synthetic chemical vitamins and the natural ones. Ascorbic acid is just as good vitamin C, for example, as one gets from an orange.

Serving on the committee as liaison representatives from the American Red Cross and the United States government services will be a number of persons, several of them well known for their research in nutrition. Among those already appointed are Colonel Paul E. Howe, Dr. W. H. Sebrell, Commander Charles S. Stephenson, Dr. William DeKleine and Dr. Louise Stanley. The following authorities on nutrition have been asked to serve as advisers to Miss Elliott. They also will be asked to serve the committee as consultants: Prof. E. V. McCollum, Dr. John R. Murlin, Prof. Mary Swartz Rose and Prof. H. C. Sherman. Ex-officio members of the committee are Mr. M. L. Wilson, of the National Defense Nutrition Program, and Dr. Robert Griggs and Dr. Lewis H. Weed, chairmen, respectively, of the National Research Council's Division of Biology and Agriculture and Medical Sciences.

THE NATIONAL YOUTH ADMINISTRATION CONTRIBUTES TO THE NATIONAL HEALTH

The National Youth Administration has launched a nationwide health program to serve the needs of young workers who are employed on its out-of-school work program. This effort to afford young people the experience of practical health education in order to help strengthen the nation's vital defenses by building a strong and healthy population will be directed along three major lines:

1. A physical appraisal, by means of a technically competent health examination, of every youth assigned to an NYA job;
2. Correction of health defects through maximum utilization of community resources, through the use of supplementary medical and dental services provided where possible by the National Youth Administration and through developing in youth an interest in improving their health by their own personal efforts;
3. Improved technical advice and assistance with respect to all NYA efforts having a direct and immediate bearing on the health of youth workers, such as nutrition, sanitation, physical development and recreation.

At the September meeting of the Conference of State and Territorial Health Officers, Aubrey Williams, National Youth Administrator, outlined the purpose and scope of the out-of-school work program. Dr. Carl E. Rice, Surgeon, U. S. Public Health Service, assigned to the National Youth Administration, presented the general plans for the health program which is under his direction. The Committee on Hospital and Medical Care of this conference endorsed the proposed program in the following resolution:

WHEREAS, The health program to be initiated by the National Youth Administration is planned to promote the health and efficiency of its enrolled youths through the utilization of health

and medical facilities which already exist, or may be supplemented by the National Youth Administration; and

WHEREAS, The program as planned seeks the active cooperation of state and local health departments: be it

Resolved, That the Conference of State and Territorial Health Officers endorse the principles and purpose of the National Youth Administration's health program; and

That the Conference recommend that the state health department serve, when requested, as co-sponsor of such statewide National Youth Administration health projects.

In addition to extending health services to youth, the National Youth Administration will continue through its work program to improve and extend community health facilities. During the year ended June 30, 1940, the record of accomplishment includes the production of over eight million articles of hospital supplies for public institutions, the construction of nine new hospitals and repairs and improvement to sixty-two others, the construction of forty other new buildings concerned with various health activities, and repairs and improvements on one hundred and thirty-one others. In addition, many young persons received work experience in a variety of hospital functions as ward attendants, laboratory assistants and kitchen and laundry workers.

The work program aims to acquaint young workers with modern production methods and prepares them for present employment conditions. Young men and young women gain practical work experience through employment on projects which produce useful articles, facilities and services for public agencies. Work experience in welding, sheet metal work, radio construction, automobile mechanics, wood working, sewing, book repair and office work is productive of articles for city and county departments and offices as police, welfare, health, education and sanitation.

As most of the National Youth Administration's work with unemployed young persons has a close relationship to the broad needs of defense, it has been designated as one of the National Defense agencies.

It is estimated that approximately five hundred thousand young persons out of school between the ages of 17 and 24 inclusive will be employed on the work program during the fiscal year. About 50 per cent of the persons so employed are young men. The average period of employment is less than one year. All of them come from families in the lower economic brackets. Increased employability and work productivity are important at all times, and especially at present.

One important aspect of the NYA work program, the operation of both resident and nonresident projects, influences the character of the health program. About fifty thousand young persons are employed on resident projects, where they live at the job site under NYA supervision twenty-four hours each day. In these resident projects the National Youth Administration must assume responsibility for the medical care of a comparatively small group of young persons. This is not true for the much larger group of employed young persons. The NYA health program is not a medical care program, as responsibility for providing medical care for intercurrent illnesses of the employed young persons will remain with the family or community except for the small group mentioned.

The health examination for all young persons will be made largely by designated practicing physicians. This examination follows a standard national form and includes provision for necessary smallpox vaccination, for routine serologic blood test and urinalysis, and for a routine chest roentgenogram or a routine tuberculin test followed by chest roentgenograms for positive

reactors. Everything possible is being done to assure the health education value of the examination. The examination is not regarded as a hurdle for young persons desiring to enter into NYA employment. The main purposes for giving the examination are to:

- (a) facilitate proper work assignment;
- (b) assist in the guidance of young persons in physical development and health education activities;
- (c) discover health conditions that need attention.

Naturally, young persons with communicable disease, severe heart lesions or mental abnormality must be excluded. It is not intended to exclude any youth from NYA employment because of physical limitations and consequent limitations in work capacity, unless such employment will endanger the life of the individual youth or will endanger the health and safety of other young persons.

The rehabilitative effort is aimed at the correction of actual and potential health hazards and those conditions which may not be health hazards but may reduce the employment possibilities and well-being of the youth. A great part of this effort will be through influencing the young people to make their own arrangements with physicians and dentists, using a portion of their NYA wage in payment for services. This will require considerable skilful counseling with the youth concerned on the part of NYA personnel. Success will depend also on the degree of consideration and cooperation given this effort by practicing physicians and dentists. In some areas, much of the necessary follow-up work can be secured through existing community agencies if such is necessary. Such facilities, however, are usually overburdened in taking care of sick people and are not particularly desirable places to send apparently healthy persons, either for examination or for corrective work.

The National Youth Administration will establish its own facilities in some regions in connection with larger projects, utilizing the services of practicing physicians and dentists in the community on a part-time basis. Local economic conditions and the presence or absence of going health facilities will indicate the necessity for NYA supplementation.

The health of NYA employees will also be approached through activities in the field of nutrition, health information, physical training and recreation.

Each state health program will be directed by a physician of outstanding professional competence who will serve on the staff of the state administrator on a part-time basis, as health consultant, to give technical supervision and direction to all NYA health efforts. Assisting him and employed on a full-time basis to direct the statewide health project is the state health supervisor. The supervisor is usually a nonmedical person selected from the fields of public health nursing or physical education or from administrative positions in public and private health associations. Statewide health projects in every state operate in collaboration with state public health departments, which in most cases are giving material assistance in the supervision and operation of NYA health activities.

One of the main jobs of the health consultant will be to assure the wise expenditure of NYA funds. Another function will be concerned with utilizing existing health facilities to the fullest extent and securing the cooperation of practicing physicians and dentists. He will also be responsible for reviewing and making recommendations concerning medical services rendered in resident centers by physicians and dentists employed on a part-time or full-time basis.

The cooperation of the medical and dental professions will be necessary to enable the plan to succeed. As the various NYA state administrators approach officials and committees of state medical and dental societies, it is hoped that the representatives of the two professions will keep in mind that the NYA health program is primarily a practical health education effort aimed at influencing the future health practices of a group of young out-of-school unemployed persons, who will usually remain in NYA employment for only a short period.

The method of attempting to accomplish this purpose will be through imparting health information, acquainting and introducing the young people to the public and private health facilities available in their own state and community, and finally by exposing them to rehabilitative health services obtainable from the private practitioner either on the youth's own initiative or through NYA supplementation as may be indicated.

NEW CORPS AREA SURGEON

Col. Joseph E. Bastion, M. C., U. S. Army, has been announced as Corps Area Surgeon of the Sixth Corps Area with station at Chicago, to succeed Col. Paul W. Gibson, M. C., U. S. Army.

COLONEL SPRUIT ASSIGNED TO GENERAL HEADQUARTERS

Lieut. Col. Charles B. Spruit, Medical Corps, U. S. Army, who has been chief of the medical division of national headquarters, Selective Service System, since last August, has been assigned to the General Staff in the War Department and will be on duty at General Headquarters, Army War College, Washington, D. C.

NEW GENERAL HOSPITAL IN THE NORTHWEST

The War Department has announced that authority has been given for the construction of a 750 bed cantonment-type general hospital at Vancouver Barracks, Washington, to serve the military personnel in the Northwest states area. This hospital will be used in connection with existing facilities at the station hospital already at Vancouver Barracks and it is expected to be ready for occupancy early in 1941.

FORT DEVENS OFFICERS FORM SCIENTIFIC GROUP

The medical officers at Fort Devens, Mass., have formed the Society of the Medical Department Officers and have been conducting scientific meetings at the station hospital on Tuesday evenings. Beginning October 8, with an address by Lieut. A. W. Bennett on "Peptic Ulcer," the speakers have included Lieut. Miles Kelly on bronchiectasis, Lieut. Charles C. Verstandig on "Roentgen Therapy in Pneumonia," Dr. E. A. Adams, Fitchburg, Mass., "Treatment of Appendicitis," Dr. Thomas H. Ham, Boston, "Hemorrhagic Diseases and Treatment," Dr. Harry Blotner, Boston, "Diabetes Mellitus," and, December 10, Dr. Atanley J. G. Nowak, Boston, "Shock." Col. H. P. Carter has been chosen president of this group and Lieutenant Verstandig, secretary.

MEDICAL CORPS ORDERS

The following orders have recently been issued to officers of the Medical Corps of the U. S. Army:

Col. Hew B. McMurdo, from the Philippine Department to be Instructor in the Medical Corps, 33d National Guard Division, Chicago area.
Col. Joseph Casper, Winthrop, Mass., retired October 31 on account of disability incident to the service.

Capt. Francis F. Viglione, from Madison Barracks, N. Y., to the Puerto Rican Department, leaving New York November 27.

Lieut-Col. Leonard W. Hassett, from Philippine Department to Fort Slocum, N. Y.

Lieut-Col. Lucius K. Patterson, from Panama Canal Department to Fort Riley, Kan.

Capt. Stephen C. Sitter and Capt. Edwin S. Kagy, from Washington, D. C., to the Philippine Department, sailing December 28.

Capt. Hubert T. Marshall, from Hawaiian Department to New York General Depot, New York Port of Embarkation, Brooklyn.

Capt. Edwin M. Goyette, from Carlisle Barracks, Pa., to Panama Canal Department, sailing January 18.

Capt. George F. Peer, from Panama Canal Department to New York Port of Embarkation, Brooklyn.

ARMY RESERVE OFFICERS

WAR DEPARTMENT

The following additional medical reserve officers had been ordered to extended active duty by order of the War Department, Washington, D. C., up to December 6:

ADAMO, Frank Scozzari, Lieut. Col., Tampa, Fla.
ALFORD, Thomas Dale, 1st Lieut., Little Rock, Ark.
BAUMHAUER, Charles Andrew, 1st Lieut., Whistler, Ala.
COSBY, Oswald Whitney, Captain, Baton Rouge, La.
CRAIN, Alfred Penn., Jr., 1st Lieut., Shreveport, La.
DAMROW, Harold Byran, Captain, Bristol, Va.
DAVIS, Richard Fleming, 1st Lieut., Batavia, N. Y.

DIODATI, Anthony Dominic, 1st Lieut., Philadelphia.
ELLIS, Herbert B., 1st Lieut., Raton, N. M.
HELLMAN, Jack M., 1st Lieut., Chicago.
LANDER, Herman Boris, 1st Lieut., Chicago.
McCLARY, George Robin, 1st Lieut., Miami, Fla.
MORRISSEY, Paul Gunkle, Jr., 1st Lieut., Nashville, Tenn.
POHL, Robert Leo, 1st Lieut., Spokane, Wash.
RAPALSKI, Adam Jozef, 1st Lieut., Nutley, N. J.
SHUTKIN, Manfred Ned, 1st Lieut., Milwaukee.
SPALDING, Joseph John, 1st Lieut., Indianapolis.
STERN, Robert Leo, 1st Lieut., Los Angeles.
STEWART, Magnus Jackson, Captain, Loveland, Col.
THAYER, Kent H., 1st Lieut., Phoenix, Ariz.
WINSOR, Carlton Webb, Captain, Detroit.

FIRST CORPS AREA

The following medical reserve corps officers had been ordered to extended active duty with the regular army by First Corps Area orders up to November 29. The First Corps Area comprises the states of Maine, Vermont, New Hampshire, Rhode Island, Massachusetts and Connecticut.

ARCHAMBEAULT, Armand C., Captain, Barre, Vt.
BLACK, Harry, 1st Lieut., Lowell, Mass.
CENTRONE, Patrick A., 1st Lieut., Middletown, Conn.
CINCOTTI, John J., 1st Lieut., Belmont, Mass.
CRAPOLICHIO, Dante V., 1st Lieut., Worcester, Mass.
CUMMINGS, Vincent P., 1st Lieut., North Adams, Mass.
DIPIPPO, Palmiro, 1st Lieut., Providence, R. I.
FRANK, Israel R., Captain, Jamaica Plain, Mass.

LANOU, William W., 1st Lieut., Pittsfield, Mass.
LEAVITT, Benjamin, 1st Lieut., Fall River, Mass.
LEVY, William S., 1st Lieut., Woonsocket, R. I.
MAHER, Joseph P., 1st Lieut., Milton, Mass.
McIVER, Frederick D., 1st Lieut., Orleans, Vt.
NATHANS, Samuel, 1st Lieut., Hope Valley, R. I.
PEKALA, Joseph G., Captain, Northampton, Mass.
QUIGLEY, George E., 1st Lieut., Newton, Mass.
RISMAN, Joseph, 1st Lieut., Lynn, Mass.
SCHILLER, Irving W., 1st Lieut., Dorchester, Mass.
SHAPIRO, Phillip, 1st Lieut., Northampton, Mass.
SHAPIRO, Robert, 1st Lieut., Roxbury, Mass.
TIEDE, Joseph W., Major, Dedham, Mass.
WEINSTEIN, Barnett, 1st Lieut., Peabody, Mass.
WILSON, William J., Jr., 1st Lieut., Derry, N. H.
YORK, Charles L., Jr., 1st Lieut., Plymouth, N. H.

SECOND CORPS AREA

The following additional medical reserve corps officers had been ordered to active duty by the Commanding General, Second Corps Area, up to December 6. The Second Corps Area comprises the states of New York, New Jersey and Delaware.

GESSNER, Gerard R., 1st Lieut., Highland Park, N. J., 3d Military Area.

HANFLING, Seymour L., 1st Lieut., Jamaica, N. Y., 2d Military Area.
LEVINE, David, 1st Lieut., New York, 2d Military Area.
MICELI, John N., 1st Lieut., Brooklyn, 2d Military Area.
MORAN, John F., 1st Lieut., Lambertville, N. J., 3d Military Area.
PERLMUTTER, Irving K., 1st Lieut., Newark, N. J., 3d Military Area.
ROBERTS, Arthur J., 1st Lieut., New York, 2d Military Area.
ROSS, Selig J., 1st Lieut., Allendale, N. Y., 2d Military Area.
SHULMAN, Bernard H., 1st Lieut., Secaucus, N. J., 3d Military Area.

THIRD CORPS AREA

The following medical reserve corps officers had been ordered to extended active duty by the commanding general of the Third Corps Area up to December 6. The Third Corps Area comprises the states of Pennsylvania, Virginia, District of Columbia and Maryland.

CLARK, Walter Scott, Jr., 1st Lieut., Burgettstown, Pa.
DEVLIN, Laurence Patrick, Captain, Philadelphia.
DONLEY, Donald, Captain, Sharon, Pa.
NATHANSON, Leon Irving, 1st Lieut., Washington, D. C.
SHAPIRO, Abraham Albert, 1st Lieut., Baltimore.
STASKIEL, Louis Julius, Jr., 1st Lieut., Glen Lyon, Pa.

FOURTH CORPS AREA

The following additional medical reserve corps officers had been ordered to active duty by Fourth Corps Area order up to December 6. The Fourth Corps Area comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana.

BLACK, Paul A. L., 1st Lieut., Wilmington, N. C.
BROWN, George C., Jr., 1st Lieut., Walterboro, S. C.
CHAMBERS, Wallace L., 1st Lieut., Pickens, Miss.
DAVIS, William B., 1st Lieut., College Park, Ga.
deCAMP, Allen L., 1st Lieut., Fayetteville, N. C.
DRISCOLL, Robert H., Captain, Newberry, S. C.
EDMONDSON, Hansel E., Captain, Edwards, Miss.
FISHER, Roy A., Jr., 1st Lieut., Knoxville, Tenn.
FOURRIER, Daniel J., 1st Lieut., Baton Rouge, La.
HALL, James B., 1st Lieut., Gainesboro, Tenn.
HUSKEY, Aubrey L., Captain, Atlanta, Ga.
JORDAN, William K., 1st Lieut., Milledgeville, Ga.
KILGH, George F., Jr., 1st Lieut., Atlanta, Ga.
McCOIN, Joseph, 1st Lieut., Lafollette, Tenn.
McGUFFIN, William C., 1st Lieut., Asheville, N. C.

MOLE, John W., Captain, Brunson, S. C.
MURPHREE, Walter E., Captain, Gainesville, Fla.
NEILL, Francis K., 1st Lieut., Albany, Ga.
NEWMAN, Lucian, 1st Lieut., Dadeville, Ala.
PROUET, Prudence E., 1st Lieut., New Orleans.
PRUSA, Victor H., 1st Lieut., Banners Elk, N. C.
RALSTON, Raymond H., 1st Lieut., Lakeland, Fla.
SPEARMAN, Walter D., Captain, Social Circle, Ga.
STEM, William A., 1st Lieut., Chattanooga, Tenn.
TANNENBAUM, Abraham J., 1st Lieut., Greensboro, N. C.
TEMPLES, Leo G., 1st Lieut., Statesboro, Ga.
WILKES, Samuel M., 1st Lieut., Laurens, S. C.

Relieved from Duty or Orders Revoked

The following officers, previously reported, have been relieved from duty or the orders have been revoked:

ARNOLD, Laurie J., Jr., 1st Lieut., Lake City, Fla.
EVANS, Milton L., 1st Lieut., Memphis, Tenn.
FERRELL, Thomas J., 1st Lieut., Waycross, Ga.
McCORD, William M., 1st Lieut., New Orleans.
VOORHIES, Norton W., 1st Lieut., New Orleans.
WORK, Samuel D., Jr., 1st Lieut., Forsyth, Ga.

FIFTH CORPS AREA

The following additional medical reserve corps officers had been ordered to active duty by Fifth Corps Area order up to November 29. The Fifth Corps Area com-

prises the states of Ohio, West Virginia, Indiana and Kentucky.

BONETA y RIOS, Thomas Luis Eusebio, 1st Lieut., McKee, Ky.
VEIRS, Everett Raymond, Captain, Ashland, Ky.

SIXTH CORPS AREA

The following additional medical reserve corps officers had been ordered by Sixth Corps Area Order up to December 6 to extended active duty. The Sixth Corps Area comprises the states of Wisconsin, Michigan and Illinois.

BARAK, Herbert G., 1st Lieut., Dixon, Ill.
BASSUENER, Reynold O., Captain, Warrens, Wis.
CONKLIN, James O., 1st Lieut., Paris, Ill.
DRESNER, Milton H., 1st Lieut., Chicago.
DUNN, Max Martin, 1st Lieut., Chicago.
FLORETH, Nelson K., 1st Lieut., Litchfield, Ill.
GAUTSCH, Joseph A., 1st Lieut., Decatur, Ill.

HILL, George R., 1st Lieut., Fairfield, Ill.
HOLNITSKY, Samuel C., 1st Lieut., Chicago.
HRINKO, Stephen A., Captain, Detroit.
JOHNSON, Clarence E., 1st Lieut., Hillsdale, Mich.
KALLEN, Irvin A., 1st Lieut., Chicago.
KAPLAN, Louis G., 1st Lieut., Chicago.
LOOBY, WILLIAM E., 1st Lieut., Highland Park, Ill.
LUETH, Harold C., Captain, Evanston, Ill.
MALOW, Louis, 1st Lieut., Chicago.
McCORMICK, Donald W., 1st Lieut., Madison, Wis.
MIDDLETON, John W., 1st Lieut., Detroit.
PYZIK, Stanley W., 1st Lieut., Chicago.
RECK, Lawrence E., 1st Lieut., Peoria, Ill.
ROBINSON, Ralph D., 1st Lieut., Moberly, Mo.
ROCCO, Paul Carl, Captain, Chicago.

SEVENTH CORPS AREA

The following additional medical reserve corps officers had been ordered to extended active duty by Seventh Corps Area Order up to December 6. The Seventh Corps Area comprises the states of North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri and Arkansas.

ARMY, Frederick Phillip, 1st Lieut., Preston, Minn., Fort Snelling, Minn.
ATKINSON, George Stanford, 1st Lieut., White Earth, Minn., Fort Snelling, Minn.
BARTON, John Currer, Captain, Independence, Iowa, Fort Snelling, Minn.
COTTRELL, Wilson Philip, Major, Reed Springs, Mo., Fort Snelling, Minn.
ENGLISH, Wallace Davis, Captain, Cardwell, Mo., Fort Snelling, Minn.
GRAY, Herschel Frederick, 1st Lieut., Little Rock, Ark., Fort Snelling, Minn.
HAENTZCHEL, Lester Esaias, 1st Lieut., Fulton, Mo., Fort Snelling, Minn.
HANNA, Joe Tyntalinio, 1st Lieut., Omaha, Fort Crook, Neb.
HARRIS, Leon Dunham, 1st Lieut., Mobridge, S. D., Fort Crook, Neb.
HEIDRICK, Paul John, 1st Lieut., Lincoln, Neb., Fort Snelling, Minn.
HEPPERLEN, Harry Michael, Captain, Beatrice, Neb., Fort Snelling, Minn.
JOHNSON, Marvin Anthon, 1st Lieut., Plainview, Neb., Fort Snelling, Minn.
KLEYKAMP, Elmer August, Jr., 1st Lieut., St. Louis, Jefferson Barracks, Mo.
KRUML, Joseph George, 1st Lieut., Ord, Neb., Jefferson Barracks, Mo.
LANNING, Robert Joseph, Captain, Junction City, Kan., Fort Snelling, Minn.
LEONARD, Roosevelt, 1st Lieut., Lyons, Kan., Fort Snelling, Minn.
LIPP, Frank Edward, 1st Lieut., Vinton, Iowa, Fort Des Moines, Iowa.
LONGO, Joseph Alfred, 1st Lieut., Omaha, Fort Des Moines, Iowa.
MACLEOD, Sherburne, 1st Lieut., Wichita, Kan., Fort Snelling, Minn.
MACAULEY, Bernard Joseph, 1st Lieut., Poplar Bluff, Mo., Fort Snelling, Minn.
NASH, Louis Rogers, 1st Lieut., Ingleside, Neb., Fort Snelling, Minn.
ORLIK, Theodore Charles, 1st Lieut., Chamberlain, S. D., Carlisle Barracks, Pa.
SALLADAY, Isaiah Reed, 1st Lieut., Pierre, S. D., Fort Snelling, Minn.

SHANE, Robert Shoemaker, Lieut. Col., Pilot Mound, Iowa, ½ The Governor, Des Moines, Iowa.
SPRONG, Aron Alfred, 1st Lieut., Sterling, Kan., Fort Snelling, Minn.
WESSLING, Alfred Louis, Major, Bethany, Mo., Fort Snelling, Minn.

To Carlisle Barracks

The following additional medical reserve corps officers have been ordered to extended active duty and are to report to Carlisle Barracks, Pa., for a one month refresher course and thence to permanent station, which will be designated by proper authority. This report dates from November 23 through November 29.

AKER, Grover Cecil, 1st Lieut., St. Louis.
BENINCASA, Anthony Vincent, 1st Lieut., St. Louis.
BLANKENSHIP, George William, 1st Lieut., Boonville, Mo.
COUGHLIN, Samuel Thomas, 1st Lieut., Larned, Kan.
DEVEREUX, James Aloysius, Captain, St. Louis.
DREY, Norman Walter, 1st Lieut., St. Louis.
FOWLER, HOLLACE Donald, 1st Lieut., Little Rock, Ark.
GUCCIONE, Joseph, 1st Lieut., St. Louis.
HAGAN, Francis James, 1st Lieut., Wichita, Kan.
HAGEN, Wayne Sigvart, Captain, Minneapolis.
HARMS, Albert Charles, 1st Lieut., Oregon, Mo.
HERMAN, Allen Isadore, 1st Lieut., Springfield, Mo.
HIRST, Otis Grady, Captain, Prescott, Ark.
JOHNSON, John Woodrow, 1st Lieut., Kerkhoven, Minn.
LITTMANN, Lewis Ezekiel, 1st Lieut., St. Louis.
MARX, Paul Donald, 1st Lieut., Lincoln, Neb.
McMILLAN, Orin Perry, 1st Lieut., El Dorado, Ark.
MOSS, Paul, 1st Lieut., Kansas City, Mo.
ODESSKY, Louis, 1st Lieut., St. Paul.
PALMER, Henry Preston, 1st Lieut., Scott City, Kan.
POTEK, David, 1st Lieut., International Falls, Minn.
RITCHIE, Elmer Joseph, 1st Lieut., North Little Rock, Ark.
SCANLAN, Jerome Edward, 1st Lieut., St. Paul.
SCHULTE, Gregory Adrian, 1st Lieut., Joplin, Mo.
WILLIAMS, Mark Frederic, 1st Lieut., Linton, N. D.

Ordered to Fort Snelling

GLEASON, Wallace Anselm, Captain, St. Paul.

NINTH CORPS AREA

The following additional medical reserve corps officers had been ordered to extended active duty by the Commanding General, Ninth Corps Area, up to December 7. The Ninth Corps Area comprises the states of Washington, Montana, Oregon, Nevada, Utah, California and Idaho.

ALNE, Arthur E., 1st Lieut., Fullerton, Calif., Presidio of Monterey and Fort Ord, Calif.
BAER, Irving N., 1st Lieut., Los Angeles, Presidio of Monterey and Fort Ord, Calif.
BARNARD, James F., 1st Lieut., Arlington, Calif., Presidio of Monterey and Fort Ord, Calif.
BIDWELL, Robert R., 1st Lieut., Santa Monica, Calif., Presidio of Monterey and Fort Ord, Calif.
CLEAVE, David C., 1st Lieut., Belvedere, Marin County, Calif., Presidio of Monterey and Fort Ord, Calif.
COLLINS, Robert F., 1st Lieut., North Hollywood, Calif., Presidio of Monterey and Fort Ord, Calif.
GENDEL, Samuel, 1st Lieut., Los Angeles, Presidio of Monterey and Fort Ord, Calif.
GOODWIN, Ralph A., 1st Lieut., Emmett, Ida., 3d Medical Battalion, Fort Lewis, Wash.
HARRISON, Alexander V., 1st Lieut., Los Angeles, Fort MacArthur, Calif. (not Fort Lewis, as stated in THE JOURNAL, December 7).

HEATH, Richard S., 1st Lieut., Inglewood, Calif., Presidio of Monterey and Fort Ord, Calif.
HORNER, Jack C., 1st Lieut., Los Angeles, Presidio of Monterey, Calif.
HUISER, George D., 1st Lieut., Richmond, Calif., Presidio of San Francisco.
KLOSS, Richard G., 1st Lieut., Oakland, Calif., Presidio of Monterey, Calif.
LAMB, Phillip V., 1st Lieut., Angels Camp, Calif., Presidio of Monterey and Fort Ord, Calif.
PASMORE, John L., Captain, Imola, Calif., Presidio of Monterey and Fort Ord, Calif.
POYAS, John L., 1st Lieut., Los Angeles, Presidio of Monterey and Fort Ord, Calif.
ROSENBERG, Ralph, Captain, San Francisco, Fort MacArthur, Calif.
ROSSI, George J., 1st Lieut., San Francisco, Presidio of San Francisco.
SHEAR, Sidney P., 1st Lieut., Los Angeles, Presidio of Monterey and Fort Ord, Calif.
SHERERTZ, Richard C., 1st Lieut., Modesto, Calif., Presidio of Monterey and Fort Ord, Calif.
TEALL, Ralph C., 1st Lieut., Sacramento, Calif., McClellan Field, Calif.

Relieved

ABRAMOPOULOS, Christos A., Major, reported ordered to extended active duty on report of week ended Nov. 8, 1940, relieved from active duty Nov. 27, 1940.

ORGANIZATION SECTION

OFFICIAL NOTES

RADIO BROADCASTS

"Doctors at Work" is the title of the sixth annual series of dramatized radio programs being presented by the American Medical Association and the National Broadcasting Company.

The series opened Wednesday, November 13, and will run for thirty consecutive weeks, closing with a broadcast from the A. M. A. meeting at Cleveland on June 3, 1941. The program is scheduled for 10:30 p. m. eastern standard time (9:30 central, 8:30 mountain, 7:30 Pacific time) over the Blue network, other N. B. C. stations and Canadian stations.

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations, and no revenue is derived from the programs. Therefore, local stations may or may not take the programs, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

Some radio stations may be unable to broadcast the program at the regular scheduled time and may transcribe and broadcast it at another hour or even on another day. It is advisable therefore to verify the time by reference to local newspapers or by telephoning the local Blue network stations.

The programs will dramatize what modern medicine offers the individual in the way of opportunities for better health and the more successful treatment of disease. Incidental to this main theme the programs will explain the characteristics of the different fields of modern medicine and its specialties.

Descriptive posters for local distribution may be had gratis from the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Program titles will be announced weekly in *THE JOURNAL* and monthly in *Hygia*, *The Health Magazine*.

Tickets are available for each broadcast. Address the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Tickets are free, but a stamped self-addressed envelop should accompany requests.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

December 25.	The Country Doctor.
January 1.*	Otorhinolaryngologist.
January 8.	Your Eyes.

* This program only will be broadcast one hour earlier than the regular scheduled time in order to clear the network for international broadcasts later in the evening.

MEDICAL ECONOMIC ABSTRACTS

MEDICAL CARE FOR MIGRATORY LABOR

The Interdepartmental Committee to Coordinate Social and Welfare Activities has recommended extension of medical care for migratory workers in the report published in the "Social Security Bulletin," September 1940, pages 3 to 15. After describing the work done in California under the Farm Security Administration, the report says:

The committee believes that federal funds should be made available through state and local agencies to assist the states in providing health and medical services for migrants. It recommends, specifically, that the federal funds made available under titles V and VI of the Social Security Act for the fiscal year ending June 30, 1941, be augmented by the sums of \$1 million and \$3 million, respectively, for the purpose of initiating a program to provide essential medical care to needy interstate migrants.

The committee also believes the successful administration of such a program demands that—

1. The state should participate financially in the program.
2. The program should provide both preventive and therapeutic services.
3. Federal funds should be available to all the states in accordance with the need for such grants.
4. The program should be applicable to all occupational groups of interstate migratory laborers.
5. Federal aid should be conditioned on provision for administration by a state agency and on states meeting within three years specified federal requirements covering length of residence within the state.
6. Social investigation, health protection and medical relief for migrants should be provided by the local agencies providing similar services for residents where such agencies exist.

AMOUNT AND TYPES OF MEDICAL CARE

The United States Public Health Service has been giving further analysis to the survey of sickness and medical care first conducted by the Committee on the Costs of Medical Care for 8,758 white families, including a total of 39,185 individuals resident "in 130 localities in 18 states representing all geographic sections."¹ The latest study of these figures is to

determine the amount and type of medical care received by these persons. The total attended cases during the year that these families were kept under observation amounted to 2.9 calls per person. The total calls for those actually attended was 4.6 per case. Eighty-one per cent were attended by private general practitioners, who made 72 per cent of all calls by any type of attendant. These figures are significant in view of the challenge frequently made of the statement that between 80 and 85 per cent of all illnesses can be adequately cared for by a general practitioner. Twelve and five-tenths per cent of all cases were attended by a specialist. Private group clinics attended only 1 per cent of the cases. Three and three-tenths per cent of the illnesses were attended by nonmedical practitioners including osteopaths, chiropractors, Christian scientists and other faith healers, naturopaths, midwives and chiropodists but not dentists.

Patients are classified according to age and sex, and when the diseases characteristic of a single case are excluded the percentage of home calls was about the same for all cases.

As might have been expected, the rate of calls per thousand of population was higher in cities of 100,000 population or more than in smaller cities and rural districts. The same percentage of difference as to population was found for non-medical practitioners.

A somewhat striking difference is found between geographic sections in respect to calls by nonmedical practitioners. Patients in the South gave the least patronage to nonmedical practitioners and California the highest, the ratio being 75 to 451. California patronage of nonmedical practitioners was more than twice as great as that of any other section of the country.

The distribution of doctors' case and call loads according to diagnosis is given in considerable detail and should be of value in calculating the probable cost of any prepayment plan for medical care. In practically all cases the greatest amount of care was required by minor respiratory disease and the second highest usually by accidents. When the cases attended by other practitioners are analyzed quite a different picture is seen. While minor respiratory is still the leading disease treated by osteopaths with rheumatic diseases second, the chiro-

1. Collins, S. D.: Frequency and Volume of Doctors' Calls Among Males and Females in 9,000 Families, Based on Nationwide Periodic Canvasses, 1828-1931, Pub. Health Rep. 55:1977 (Nov. 1) 1940.

practor reverses this order. "Backaches and other ailments" occupy the third place with both, while "nervous" receives much more attention by these types of practitioners than by physicians. When it comes to the number of calls, rheumatic diseases lead in the practice of both osteopaths and chiropractors, making up 13.6 and 14.1 per cent of their entire practice, while they require but 3.2 per cent of the care given by gen-

eral practitioners. The report of the Public Health Service comments on this feature as follows:

The lack of definite diagnoses for illnesses treated only by nonmedical practitioners tends to increase the number of ill defined cases; in spite of this tendency the picture seems reasonably true, namely that it is the various rheumatic and other indefinite chronic pains that bring the patient to a nonmedical practitioner. Aside from this, sprains and other cases where massage therapy is commonly applied also fall into the hands of such practitioners.

WOMAN'S AUXILIARY

Delaware

The annual meeting of the auxiliary to the Delaware Medical Society met in Rehoboth, October 3, with thirty-eight members present.

Weekly meetings for Red Cross work were voted on. A committee was appointed to collect clothes for the British War Relief.

Dr. A. R. Shands, the guest speaker, spoke on the recently opened Nemours foundation, a hospital for crippled children of Delaware.

Iowa

At the executive board meeting of the woman's auxiliary to the Iowa State Medical Society in Des Moines, September 16, Mrs. V. E. Holcombe, national president, addressed the group on the increasing influence and responsibility of women. Also present were Dr. James C. Hill and Dr. John G. de Bey, members of the advisory council. Each addressed the group, giving valuable suggestions regarding the role of the doctor's wife as an individual and the auxiliary as a unit in promoting medical interests.

A recent addition to the state organization was reported as the Upper Des Moines Auxiliary, comprising the counties of Emmet, Dickinson, Clay and Palo Alto.

Nebraska

The auxiliary to the Lancaster County Medical Society met October 7. The speaker was Prof. O. H. Bimson of Lincoln High School, who talked on his experiences as a member of the Educational Policies Commission and the American Youth Commission.

The Omaha-Douglas county medical auxiliary held a Harvest Home Benefit Dinner October 9. Proceeds from the dinner will benefit the projects adopted at the recent membership tea: namely subscriptions to *Hygeia* to all 102 of Omaha's public and parochial schools and contributions to the Community Chest, the School Free Lunch Fund and the Nebraska Tuberculosis Health Camp.

A joint meeting of the tri-county auxiliary No. 1 and the Tri-County Medical Society was held recently at the St. Francis Hospital in Grand Island. The nurses' glee club sang during the dinner hour. At the auxiliary meeting after reports were given by committee chairmen Mrs. Elmer Hansen spoke on auxiliary problems; Mrs. J. G. Woodin, president of the auxiliary, gave a talk on "A Look Ahead," and Mrs. A. D. Broun, state president, addressed the group.

The Woman's Auxiliary to the Adams County Medical Society met at Ingleside. Mrs. L. W. Rork presided. There was a business meeting preceded by a musical program given by the occupational therapy department at Ingleside.

New York

The Woman's Auxiliary to the Albany County Medical Society entertained, September 17, the wives of members of the third district branch to the state medical society, which includes Schoharie, Albany, Rensselaer, Greene, Columbia, Sullivan and Ulster counties. The auxiliaries of Columbia County and of Albany County held their regular meeting at this time and invited doctors' wives of unorganized counties. October 23, the Albany auxiliary was addressed by Dr. Louis Bauer, a member of the medical preparedness committee of the New York State Medical Society.

At the annual dinner of the auxiliary to the Cayuga County Medical Society the sum allotted for the dinner was presented to the American Red Cross. Mrs. G. B. Adams, president-elect

of the woman's auxiliary to the state society, was guest of honor at a tea to which members of the Onondaga County auxiliary were present.

The auxiliary to the Essex County Medical Society was organized, June 4, at the semiannual meeting of the society. Mrs. G. Scott Toune, past state president, Mrs. T. C. Bullard of Saratoga and Mrs. R. F. Johnson of Cayuga gave talks. With the organization of the Essex County auxiliary there are twenty-four counties organized in New York State.

The first meeting of the year in Nassau County was a membership tea, September 24. Guests were greeted by the president of the auxiliary, Mrs. A. C. Martin, and by Dr. Aaron Higgins, president of the county medical society.

The fourth district branch of the state medical society held its annual meeting in Schenectady October 1 and 2. The wives of all the doctors in the district were entertained by the auxiliary. The presidents of counties having auxiliaries acted as hostesses for the day and the wives of the presidents of the unorganized counties and wives of the officers of the district branch were guests of honor.

Ohio

A meeting of the executive board of the Woman's Auxiliary to the Ohio State Medical Association was held in Columbus, October 9, with Mrs. J. Edwin Purdy, the president, presiding. She expressed appreciation that all the members were present and then introduced Mrs. V. E. Holcombe, the national president. Mrs. W. H. Curtiss, Chairman of Organization, reported that about forty counties had organized. The meeting adjourned, to meet in Cleveland in June.

Utah

The auxiliary to the Weber County Medical Society held its first meeting of the year on Monday, October 7, at the home of Mrs. Joseph R. Morrell in Ogden. "Health Insurance" was discussed by Dr. G. M. Fister, and there was music by Mrs. O. S. Daines. Mrs. A. Z. Tanner, Layton, the new president, was in charge.

The Salt Lake County medical auxiliary held a meeting at the Hotel Utah Roof Garden. The first speaker was Dr. E. M. Neher, advisory chairman. The new officers were introduced, and Mrs. John Z. Brown gave some history of the Salt Lake County organization. She introduced those who were present who had served as presidents. Dr. Dee L. Folsom of the Salt Lake Dental Society spoke in the interests of impending legislation of interest to both dentists and doctors in Utah and Salt Lake City.

Wisconsin

The Woman's Auxiliary to the Douglas County Medical Society, with Mrs. E. A. Myers presiding, met October 7 in Superior. Miss Aimee Zillmer of the state health department spoke on "Social Hygiene." For a special project Miss Zillmer was kept in the county for two weeks, being presented to twelve different civic organizations, including all of the P. T. A. groups in the city of Superior, all of the junior and senior high schools in the city and county, the Teacher's College and some special classes in the college.

Red Cross work was started in November by the Manitowoc County auxiliary, of which Mrs. Theodore Tietgen of Manitowoc is president.

The Washington-Ozaukee auxiliary is taking up Red Cross work. At the October 10 meeting two members volunteered to knit and twelve to sew. Mrs. A. H. Heidner of West Bend is the new president.

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 2227.

CALIFORNIA

Surgical Meeting.—The Los Angeles Surgical Society held its annual meeting, December 13, with Dr. Rolland Russell Best, associate professor of surgery, University of Nebraska College of Medicine, Omaha, as the guest speaker. His subject was "Indications for the Biliary Flush." Others on the program included:

Dr. George Lawrence Chaffin, Ruptured Diverticulitis of the Colon.
Dr. Emmet A. Pearson, Heterotopic Endometriosis.
Dr. Charles W. Reeder, Long Beach, Idiopathic Segmental Infarction of the Greater Omentum.
Dr. William H. Snyder Jr., Extensive Carbuncle of the Neck.
Dr. Arthur E. Smith, Bilateral Condylar Fracture in a Patient with Multiple Fractures of the Mandible.

Breakfast Club Organized.—Forty-five members of the staff of the Methodist Hospital of Southern California, Los Angeles, have organized a breakfast club which meets at the hospital on the first and third Wednesday morning of the month. Each meeting starts at 7:30 a. m. and ends promptly at 9. Chairmanship of each meeting is chosen by lot. Two cases are presented which have been previously abstracted from actual case reports. Copies are distributed for perusal during breakfast. The names of patient and physician are withheld to stimulate informality and freedom of discussion. A name is drawn from those present and this physician may ask any questions to work up the case. He gives the diagnosis and outlines the treatment that he would follow. This is compared with the chart diagnosis and treatment and general discussion follows. Each of these two cases takes twenty-five minutes, after which a short prepared paper of interest to all is given by one of the members.

ILLINOIS

Conference on Public Health.—The Illinois Conference on Public Health was held in Springfield, December 5-6. Among the speakers were:

Dr. Halbert L. Dunn, Washington, D. C., Using Vital Statistics as a Program Guide.
Howard J. Shughnessy, Ph.D., Chicago, Milk-Borne Disease.
Dr. Robert S. Breakey, Lansing, Mich., Sex Education in High Schools.
Dr. Harry S. Mustard, New York, Public Health in National Defense.
Dr. Richard E. Shope, Princeton, N. J., Epidemiology of Virus Diseases.
Dr. Donald K. Hilbs, Chicago, Chemotherapy in the Treatment and Control of Gonorrhea.

Chicago

Activities of Tumor Institute.—The Chicago Tumor Institute has issued a report of its activities for its first two years. Of 904 patients observed, 613 patients had cancerous lesions, while 301 had benign tumors, inflammatory lesions and other noncancerous conditions. It is of special significance, says the report, that of the 613 cancer patients 262, or 42.7 per cent, had far advanced cancers, and it is sad to reflect that the greater number were cases of accessible forms of cancer easily curable in early stages. Of the total number of patients, 622 were residents of Chicago, 140 came from cities in Illinois outside of Chicago, 130 from twenty-four other states and 12 from six foreign countries. Procedures carried out included 13,269 examinations, 8,846 roentgen diagnoses, 7,756 roentgen treatments, 4,432 radium treatments, 184 minor surgical procedures, seventy-eight surgical procedures, and the making of 278 photographs and lantern slides. An attempt is being made to pursue a five year follow-up of all cancer patients treated at the institute and in the group of 904 observed only 1 patient remained untraced at the end of the first two years. Every patient who was treated has been traced. "Cancerphobia" is attributed to 34 patients of the 904 who came to the institute because of fear they were suffering from cancer. The disease was not found in any of this group. Seventeen, or 50 per cent, are classified as having general phobias, and of the remainder

one third referred their complaints to the breast, one third to the mouth and one third to the gastrointestinal and genito-urinary systems. In the first two years, two courses have been held and instruction has been given to forty-nine qualified radiologists, thirty-six from the United States and thirteen from foreign countries. Eighty physicians from thirty foreign countries visited the institute to study its organization and equipment and consult with the staff on various phases of the cancer problem. The institute was opened in March 1938 and the report covers the period ended March 31, 1940.

INDIANA

Chief of Local Health Administration.—Dr. George M. Brother, Rising Sun, formerly director of district health unit number 4, has been appointed chief of the bureau of local health administration of the state board of health. He succeeds Dr. John W. Ferree, Indianapolis, who recently became director of the board of health. Dr. Brother recently took a degree in public health at Johns Hopkins University School of Hygiene and Public Health, Baltimore. He graduated at Indiana University School of Medicine, Indianapolis, in 1934.

IOWA

Aid for Research.—Grants-in-aid for research have been received recently by the following staff members of the State University of Iowa College of Medicine, Iowa City: Harry M. Hines, Ph.D., of the department of physiology, \$5,000 from the National Foundation for Infantile Paralysis for study of regeneration of nerve and muscle; Dr. William D. Paul of the department of theory and practice, \$3,500 from the Emerson Drug Company for the study of the action of bromides, and Dr. Philip C. Jeans of the department of pediatrics, \$3,000 from the Mead Johnson Company for a continuation of studies on infant nutrition.

KANSAS

Society News.—Dr. Willis H. McKean, Kansas City, addressed the Wyandotte County Medical Society, November 19, on "Surgical Treatment of Empyema" and Dr. Maurice A. Walker, Kansas City, "Minor Surgery in the Office."—Drs. Fred J. McEwen and James B. Fisher addressed the Sedgwick County Medical Society in Wichita, November 19, on "Pulmonary Embolism" and William P. Callahan, "Medical Preparedness." Drs. Rolland Russell Best and Frank Lowell Dunn, both of Omaha, presented the program before the society, November 6; their subjects were, respectively, "Biliary Flush as an Aid in Surgery and Medical Treatment of Biliary Tract Diseases" and "Modern Undernutrition."

LOUISIANA

Changes in Health Officers.—Dr. William C. Summer, Minden, director of the Webster Parish health unit for the past ten years, has resigned to become consultant adviser to the parish health units in eighteen parishes of northern Louisiana. He will be succeeded by Dr. Edmond G. Klamke, New Roads, health director of Pointe Coupee Parish.—Dr. John M. Whitney, Jennings, head of the Jefferson Davis Parish health unit, has been made director of fifteen parish health units in southwestern Louisiana; the area runs from the Texas line to Terrebonne Parish on the south to Pointe Coupee Parish on the north.

Refresher Course.—A refresher course in obstetrics will be conducted at the Louisiana State University Medical Center, January 6-18. The group is limited to eight physicians, so that each may receive individual attention. Additional courses will be offered later in the year. The course is being financed by social security funds allocated to the state by the Children's Bureau, U. S. Department of Labor. Applications of physicians interested in taking the course should be sent to the Maternal and Child Health Division, 313 Civil Courts Building, New Orleans, on or before December 1. Applications will be reviewed by a committee from the state medical society, who will select the physicians to take the course.

NEW JERSEY

District Meeting.—Dr. Frank H. Lahey, Boston, President-Elect of the American Medical Association, addressed a meeting of the Fifth Council District of the Medical Society of New Jersey, December 19, in Woodbury, on "Management of Diseases of the Thyroid." The Gloucester County Medical Society was host.

Special Society Meeting.—Dr. Hyman I. Goldstein, Camden, was elected president of the New Jersey Gastroenterological Society at its annual meeting in Newark, December 2. Dr. Harrison R. Wesson, Montclair, was elected vice president and Dr. Sydney Rosenthal, Newark, secretary. A public meeting will be held by this society February 3, at which a symposium on "Ulcer of the Stomach and Duodenum" will be presented.

NEW YORK

The State Society's Postgraduate Courses.—The council committee on public health and education of the Medical Society of the State of New York has arranged several courses for county societies. A course on general medicine is being presented before the Schoharie County Medical Society on Tuesday afternoons at Cobleskill and the Montgomery County society Tuesday evenings at Amsterdam with the following speakers:

November 19, Dr. David D. Moore, New York, Diabetes Mellitus.
November 26, Dr. Kenneth R. McAlpin, Williamstown, Mass., A General Consideration of Anemia, Both Primary and Secondary.
December 3, Dr. Harold J. Stewart, New York, Digitalis Therapy: Mechanism of Its Action in Congestive Heart Failure.
December 10, Dr. Albert Vander Veer, New York, Asthma.
December 17, Dr. Leslie P. Barker, New York, Syphilis.
January 7, Dr. Homer F. Swift, New York, Rheumatic Fever.
January 14, Dr. John D. Lyttle, New York, Nephritis.

Two courses are in progress for the Nassau County Medical Society. One on pediatrics, arranged in cooperation with the state department of health, has the following schedule:

November 25, Dr. Charles Hendee Smith, New York, Diet of Infants and Children.
December 23, Dr. Hugh Chaplin, New York, Care and Feeding of Prematures.
January 27, Dr. Gaylord W. Graves, New York, Preventive Pediatrics and the Periodic Health Examination.
February 24, Dr. Philip M. Stimson, New York, The Infectious Diseases.
March 24, Dr. Frederick H. Wilke, New York, The Anemias of Childhood.
April 28, Dr. Katharine G. Dodge, New York, Rheumatic Fever, Chorea and Heart Disease.

The following speakers are announced for a course in general medicine in Nassau County:

November 18, Dr. Ralph G. Stillman, New York, The Significance of Laboratory Tests and Methods in the Practice of Medicine.
December 16, Dr. Harry H. Gordon, New York, Endocrine Problems in Adolescence.
January 20, Dr. Norman H. Plummer, New York, Newer Chemotherapeutic Methods.
February 17, Dr. Norman H. Jolliffe, New York, The Relation of Vitamins to Disease.
March 17, Dr. Edward M. Livingston, New York, Abdominal Pain.

New York City

Public Lectures.—The New York Academy of Medicine opened its sixth annual series of "Lectures to the Laity," November 14, with the Linsly R. Williams Memorial Lecture, by Dr. Alan Gregg, on "Humanism and Science." Others in the series are as follows:

Dr. William Healy, Boston, Psychiatry and the Normal Life, December 12.
Dr. Henry E. Sigerist, Baltimore, Paracelsus in the Light of Four Hundred Years, January 23.
Dr. Francis Carter Wood, New York, What We Do Know About Cancer, February 27.
Irwin Edman, Ph.D., New York, Philosophy as Therapy, March 27.
Oscar Riddle, Ph.D., Cold Spring Harbor, The Promise of Endocrinology, April 24.

Dr. Meleney Comes to New York University.—Dr. Henry E. Meleney, associate professor of preventive medicine and public health at Vanderbilt University School of Medicine, Nashville, Tenn., has been appointed Hermann M. Biggs professor of preventive medicine at New York University College of Medicine, effective April 1, 1941. Other appointments announced are:

Dr. Conrad Berens, associate professor of ophthalmology.
Dr. Wendell L. Hughes, clinical professor of ophthalmology.
Dr. Charles W. Lester, assistant clinical professor of surgery.

Dr. Robert F. Pitts, instructor in physiology, has been promoted to assistant professor of physiology.

Dr. Mustard Honored.—The Alumni Association of the De Lamar Institute of Public Health, Columbia University College of Physicians and Surgeons, gave a dinner, November 19, at the Hotel George Washington in honor of Dr. Harry Stoll Mustard, director of the institute. Leonard J. Ciccoli, Ph.D., president of the association, presided, and the speakers were Drs. Mustard; Wilson G. Smilie, professor of public health and preventive medicine, Cornell University Medical College, and Comdr. Charles S. Stephenson, an alumnus, in

charge of the division of preventive medicine, Bureau of Medicine and Surgery, U. S. Navy. Dr. Mustard was appointed last April to succeed Dr. Haven Emerson as director of the institute.

NORTH CAROLINA

Anniversary at Duke University.—The tenth anniversary of Duke University School of Medicine and Duke Hospital, Durham, was observed, November 29-30. An addition to the hospital and a new department of psychiatry were dedicated. Dr. Adolf Meyer, Henry Phipps professor of psychiatry of the Johns Hopkins University School of Medicine, Baltimore, conducted a clinic to mark the opening of the new psychiatric wards, which are named in his honor. The wards provide eighteen beds for the use of the new department. Dr. Richard S. Lyman, formerly of Baltimore, has been appointed professor of psychiatry. The new hospital wing is five stories high and has two hundred rooms providing one hundred and thirteen additional beds and eighty new offices and examining rooms. At the ceremony Dr. Frederic M. Hanes, Florence McAlister professor of medicine, presided. The speakers were Robert L. Flowers, acting president of the university, and Dr. Wilburt C. Davison, dean of the school of medicine. Another feature of the two day program was a clinic at which Dr. Jay M. Arena presided, and addresses were made by Drs. Hanes, David T. Smith, Julian Deryl Hart and Francis Bayard Carter. At a dinner, Friday, at the University Union, the alumni association was formally organized, with Drs. Arena as president; Robert W. Graves, vice president, and J. Lamar Callaway, secretary. All are on the Duke Hospital staff. Duke Hospital received its first patient July 21, 1930, and has since received more than 143,000 patients. The school of medicine opened in October 1930 and has graduated 374 physicians.

OHIO

The Lower Lecture.—Edward A. Doisy, Ph.D., professor of biochemistry, St. Louis University School of Medicine, delivered the third annual Lower Lecture of the Academy of Medicine of Cleveland, November 15. His subject was "Vitamin K and Other Antihemorrhagic Compounds."

Personal.—Dr. Torald H. Sollmann, dean and professor of pharmacology and materia medica, Western Reserve University School of Medicine, Cleveland, received the "degree of merit" of Nu Sigma Nu at the annual convention of the fraternity in Detroit, November 23.—Dr. James C. Elder, Millersburg, has resigned as health officer of Holmes County.

Society News.—Dr. John Scudder, New York, addressed the Academy of Medicine of Cincinnati, November 19, on "Shock: Blood Studies as a Guide to Therapy."—Dr. Edward H. Ryneerson, Rochester, Minn., addressed the Stark County Medical Society, Canton, November 14, on "Diabetes Mellitus and Hyperinsulinism."—A symposium on "Low Back Pain" was presented at a meeting of the Columbus Academy of Medicine, November 18, by Drs. Judson D. Wilson on "Injury to Articular Facets"; Roy J. Secrest, "Herniated Intervertebral Disk," and Harry E. Le Fever, "Hypertrophied Ligamentum Flavum."—Dr. Robert R. Crawford, Mansfield, addressed the Ashland County Medical Society, Ashland, November 15, on the care of fractures.—Dr. Harold Feil, Cleveland, discussed "Cardiac Emergencies and Their Treatment" at a meeting of the Lorain County Medical Society, Elyria, November 12.—Dr. Carlo J. Tripoli, New Orleans, addressed the Montgomery County Medical Society, Dayton, November 15, on "New Developments in the Treatment of Meningitis."

PENNSYLVANIA

Society News.—Dr. Newlin F. Paxson, Philadelphia, addressed the Delaware County Medical Society, Chester, November 14, on "Chronic Nephritis and Pregnancy."—Dr. George P. Müller, Philadelphia, addressed the Cambria County Medical Society, Johnstown, November 14, on "Cancer of the Stomach."—The Lycoming County Medical Society held an all day meeting in Williamsport, November 8, with the following speakers: Drs. Leonard G. Rowntree, Philadelphia, on cardiovascular disease; Lewis C. Scheffey, Philadelphia, on gynecology; Harrison F. Flippin, Philadelphia, and Dale C. Stahl, Harrisburg, a symposium on pneumonia.—The annual William Moore Guilford Memorial Clinic was presented by the Lebanon County Medical Society, Lebanon, November 26. Dr. Baldwin H. E. W. Lucke, Philadelphia, conducted the clinic on "Edema of Renal Origin."—Dr. Marshall M. Lieber, Philadelphia, addressed the Washington County Medical Society, Washington, November 6, on "Newer Concepts on the Mechanism of Inflammation and Shock—Some Practical Considerations."

GENERAL

Outbreaks of Influenza.—An extensive outbreak of an apparently mild type of influenza was reported December 16 in Alexandria, La. This city has recently nearly doubled its normal population of 30,000 owing to the influx of army camp workers and others who have flocked there in view of the military training program at Camp Beauregard nearby. Several thousand cases of influenza are said to have developed chiefly among the camp construction workers and others, many of whom were living under unsatisfactory housing conditions. No cases were reported among the soldiers at Camp Beauregard. The *Chicago Tribune* reports that the influenza epidemic in the Western states, now waning in California, has spread to Washington and Oregon. Schools were closed in Bellingham, Wash., December 13 and in Portland December 16. Influenza has also been reported in Texas and Kentucky.

Grants for Research in Endocrinology.—Requests to the National Research Council Committee for Research in Endocrinology for aid during the fiscal period from July 1, 1941 to June 30, 1942 will be received until Jan. 31, 1941. Application blanks may be obtained by addressing the Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington, D. C. In addition to a statement of the problem and research plan or program, the committee wants information on the proposed method of attack, the institutional support of the investigation and the uses to be made of the sum requested. No part of any grant may be used by the recipient institution for administrative expenses. Applications for aid of endocrine research on problems of sex in the narrower sense cannot be given favorable consideration, but the committee will consider support of studies on the effects of sex hormones on nonsexual functions, for example on metabolism.

Fund Available for Research.—The next meeting of the American Academy of Arts and Sciences to consider applications for assistance in scientific research will be held February 15. Income from the Permanent Science Fund, according to agreement and declaration of trust, shall be applied by the academy to such scientific research as shall be selected "... in such sciences as mathematics, physics, chemistry, astronomy, geology and geography, zoology, botany, anthropology, psychology, sociology and economics, history and philology, engineering, medicine and surgery, agriculture, manufacturing and commerce, education and any other science of any nature or description, whether or not now known or now recognized as scientific, and may be applied to or through public or private associations, societies, or institutions, whether incorporated or not, or through one or more individuals." Additional information may be obtained from the chairman of the Committee on the Permanent Science Fund, Prof. John W. M. Bunker, Massachusetts Institute of Technology, Cambridge, Mass.

Psychiatric Association Plans Public Education Program.—The committee on public education of the American Psychiatric Association announces the appointment of twelve regional chairmen to cooperate with the press and otherwise "to foster the dissemination of sound psychiatric information to the public." The chairmen are Drs. Franklin G. Ebaugh, Denver; Ralph C. Hamill, Chicago; Titus H. Harris, Galveston, Texas; Richard H. Hutchings, Utica, N. Y.; George S. Johnson, San Francisco; William C. Menninger, Topeka, Kan.; Merrill Moore, Boston; Arthur P. Noyes, Norristown, Pa.; Winfred Overholser, Washington, D. C.; Thomas A. Ratliff, Cincinnati; Newdigate M. Owensby, Atlanta, Ga.; and Karl M. Bowman, New York. In addition to providing the press of these regions with an authoritative source of information on psychiatric matters, the association will stress its policy with regard to mental hospital standards, it was said. "One of the principal aims of this organization will be to acquaint the public with the fact that a well staffed, well equipped hospital for the care of the mentally ill is not a luxury, but a basic necessity in any civilized community," the statement said.

Annual Forum on Allergy.—Allergists of the Middle West will hold their third annual forum to review progress in the clinical study of allergy in Indianapolis, January 11-12, at the Claypool Hotel. Methods of instruction will include study groups under different instructors, exhibits, special lectures, question and answer periods and symposiums. The annual Forum Lecture will be delivered Sunday by Dr. Bela Schick, New York, on "Allergy, Hypersensitiveness and Immunity." Dr.

Schick will receive a gold medal honoring him for "distinguished and outstanding contributions in the field of allergy." The other special lectures will be delivered by Dr. Albert D. Ruedemann, Cleveland, on "Allergic Manifestations in the Eye," and by Dr. Malcolm M. Cook, St. Louis, "Water and Electrolyte Metabolism in Allergy." The symposiums will be on "Bronchial Asthma," with Dr. Ben Z. Rappaport, Chicago, as moderator; "Insects as Allergens," Dr. Harry L. Huber, Chicago, and "Allergic Headache," Dr. Theodore L. Squier, Milwaukee. All physicians in good standing in their local medical societies will be welcome. There will be a registration fee of \$5. Registrations should be mailed to Dr. Tell Nelson, 636 Church Street, Evanston, Ill.

Special Society Elections.—Dr. John H. Moore, Grand Forks, N. D., was chosen president-elect of the Central Association of Obstetricians and Gynecologists at its recent annual session in Indianapolis and Dr. Thomas B. Sellers, New Orleans, was installed as president. Other officers include Drs. Minnie L. Maffett, Dallas, vice president, and William F. Mengert, Iowa City, secretary-treasurer. New Orleans was selected as the place of the 1941 meeting, the exact date to be announced later.—Dr. Bruce H. Douglas, Detroit, was elected president of the Mississippi Valley Conference on Tuberculosis at the annual meeting in St. Paul, October 2-4. Donald E. Pratt, executive secretary of the Missouri Tuberculosis Association, was elected vice president, and A. W. Jones, executive secretary of the St. Louis Tuberculosis and Health Society, was reelected secretary. Dr. George C. Turner, Chicago, was elected president of the Mississippi Valley Sanatorium Association, which met in conjunction with the tuberculosis conference. Dr. Francis F. Callahan, Pokegama, Minn., was elected vice president and Dr. Henry S. K. Willis, Northville, Mich., secretary.—Dr. Marcus Pinson Neal, Columbia, Mo., was chosen president-elect of the Southern Medical Association at the annual meeting in Louisville, Ky., November 12-15. Dr. Paul H. Ringer, Asheville, N. C., was elected president, taking the place of Dr. Quitman U. Newell, St. Louis, the president-elect, who died a few days before the meeting. Drs. Ernest Lee Heflin, Louisville, and James R. Bloss, Huntington, W. Va., were elected vice presidents. Next year's meeting will be in St. Louis.—Ernest Carroll Faust, Ph.D., New Orleans, was chosen president-elect of the American Society of Tropical Medicine at its annual meeting in Louisville, Ky., November 12-15, in conjunction with the Southern Medical Association. Dr. Thomas T. Mackie, New York, was installed as president; Dr. Fred L. Soper, Rio de Janeiro, Brazil, was made vice president, and Dr. E. Harold Hinman, Wilson Dam, Ala., secretary.—Dr. Earl E. Kleinschmidt, Chicago, was chosen president-elect of the American School Health Association at its recent annual meeting and Dr. Amos L. Beagler, Denver, was inducted into the presidency. Dr. Helen Irene Ahrens Cary, Portland, Ore., and Lon W. Morrey, D.D.S., Chicago, were chosen vice presidents. Dr. Arville O. DeWeese, Kent, Ohio, is the executive secretary-treasurer.—Gobind Behari Lal, New York, science editor of International News Service and the Hearst newspapers, was elected president of the National Association of Science Writers at its annual meeting. Robert D. Potter, science editor of the *American Weekly*, New York, is vice president; Miss Jane Stafford, medical writer, Science Service, Washington, D. C., secretary, and Stephen J. McDonough, science writer, Associated Press, Washington, treasurer.

Government Services

The Government Needs Technicians

The U. S. Civil Service Commission requests applications for positions as senior medical technician at \$2,000 a year, medical technician at \$1,800, and assistant medical technician at \$1,620. The senior technician may offer general subjects or specialize in roentgenology; the medical technician and the assistant may have their choice of surgery, roentgenology or general subjects. This announcement is an amendment of an earlier one which did not include "general" in the optional subjects. Applications must be on file with the commission at Washington, D. C., not later than December 30 if from states other than the following: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming. For the Western states the deadline is January 2.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 13, 1940.

The Chemotherapy of War Wounds

At the Medical Society of London a discussion took place on chemotherapy in war wounds. Col. Max Page said that it was not until 1939 that surgeons took any interest in the use of sulfonamide derivatives in the treatment of wound infection. Experimental work, mainly on mice, indicated that they had a prophylactic value. Plans were made for trying them in the war, but the nature of the campaign in France and Flanders allowed only sporadic attempts as far as recorded evidence went. His own impression was that the incidence of secondary infection in wounds treated with sulfanilamide was lower than might have been expected from the last war. The condition in which prophylactic use of a sulfonamide was probably good was a late wound, twenty-four or thirty-eight hours or perhaps a week after infection, requiring operation and suggesting the possibility of a flare-up. If a full dose was given by mouth beforehand, intervention would be safer. In treatment a few doses would on most occasions deal with an acute streptococcal infection but not with a chronic infection. When the infection was in the blood the drug was not of the same value as when it was in the body tissues. The same held for gas gangrene.

Colonel Colebrooke said that definite results were to be expected from careful use of sulfonamide derivatives. The first was the prevention of hemolytic streptococcus infection. But the great majority of the wounded in war were not infected with hemolytic streptococci at the time of the injury. Their infection occurred at any time within a week afterward as a hospital infection. A sulfonamide derivative would be valuable in a case of secondary operation in which there was a suspicion of hemolytic streptococcus infection. Prophylactic treatment should be administered in four hourly doses. It might also be possible to arrest infection by prompt and vigorous action. In long-standing or superficial cases, such as old burns and road accidents which had led to infection, the application of sulfanilamide powder gave astonishingly good results.

Mr. W. H. Ogilvie said that infection seemed to be a far less serious problem in this war than in the last. The explanation was not simple. The wounded were far less fatigued and dehydrated; their clothes were cleaner; many of the weapons were less damaging to the tissues than the shell and hand grenades which were so much used in the last war. He thought that the streptococci and anaerobic organisms of today were feeble compared with their ancestors of 1914-1918. But after making these allowances much credit must go to chemotherapy. In the wounded from the evacuation of Dunkirk chemoprophylaxis when started early put the patients in good condition, while those who arrived infected at the hospital in whom chemotherapy was started immediately after débridement soon showed repair and clean granulation. The contrast between the wounds of those who had been given a sulfonamide derivative in transit and those who had not was great. The latter when admitted two or three days after being wounded were most heavily infected. On being put on a sulfonamide derivative they had a temperature which rarely rose above 100 F. or remained elevated more than three or four days. Sir Thomas Dunhill referred to 65 patients treated in the hospital, all extremely ill. Their knees and elbows were shattered and ankles broken. Pus was soaking through the plaster, and the stench was beyond belief. In the last war he would have felt that three fourths would require amputation and that streptococcal septicemia would occur. They were treated by fixation and a sulfonamide derivative for a number of days until it was felt that appropriate doses had been

given. Two died from secondary hemorrhage and one from gas gangrene, but all the rest did well. He believed that three fourths of the results was due to fixation and the rest to the sulfonamide derivative. Together they seemed to be able to scotch the spread of infection.

Gas Gangrene

The War Wounds Committee of the Medical Research Council and the Committee of London Sector Pathologists have published a review of gas gangrene based on the experience of the last great war and on recent experience in Spain, France and elsewhere. As these committees are composed of leading surgeons and pathologists the pamphlet, which is published by the government, is authoritative. For prophylaxis, excision of contaminated war wounds at the earliest opportunity is recommended. But when injured men come under observation only at a later period, when organisms have already reached the living tissues bordering on the wound cavity or when the wound is passing through a stage of physiologic reaction to injury, the time for prophylactic excision has passed and the surgeon should aim at providing adequate drainage by incision. In late cases, however, in which there is any suspicion of gangrenous infection of muscle, the wound must be opened up and the muscles implicated must be ruthlessly excised.

Recent laboratory experiments indicate that the best available treatment, in addition to surgery, for the established disease is a combination of antitoxin and chemotherapy with sulfapyridine or sulfanilamide. The serum and the drug seem to have a synergic action, the former neutralizing the bacterial toxin, while the latter exercises a bacteriostatic effect on the organism. The antitoxin should be administered, preferably intravenously, at the earliest possible moment. The dose of polyvalent antitoxin recommended is 7,500 international units of *Clostridium welchii*, 3,750 of *Clostridium septicum* and 2,500 of *Clostridium oedematiens*, repeated as necessary. The first dose of sulfapyridine or sulfanilamide should be 2 Gm. dissolved in hot citric acid or lemon solution. Subsequent doses, starting two hours later and continued four hourly for two days, should be 1 Gm. uncrushed. After the first two days the dose should be gradually reduced as the condition improves, but the interval between the doses should not be more than six hours for several days. Small doses, e. g. 3 Gm. daily, should be continued for three or four days after the temperature has become normal. The duration of treatment and the total dosage will vary somewhat, but the latter should seldom exceed 35 Gm.

In cases in which the surgeon has to operate on a wound in which anaerobic infection is already established, preoperative sulfapyridine or sulfanilamide by mouth and antitoxin intravenously may be useful in preventing the spread of infection. The first dose of the drug should be 3 Gm., which should, if possible, be given two hours before operation so as to secure a high concentration in the blood when the wound is disturbed.

Marriages

DAVID BRAINARD GREGG, Greensboro, N. C., to Miss Mary Page Newton of Charleston, S. C., October 17.

WILLIAM C. BEHEN, Lansing, Mich., to Miss Rose Lucille Megerle of Newport, Ky., October 14.

DUWARD O. WRIGHT, Fort Payne, Ala., to Miss Harriet D. Harton at Conway, Ark., October 5.

JOHN J. SCHOFF, Media, Pa., to Miss Charlotte Fullerton of Swarthmore, November 8.

DAVID ROSENBLUM to Miss Esther Shamir, both of Los Angeles, September 21.

JOHN JIBB THORNTON to Miss Marion Faye Gager, both of Cleveland, October 11.

Deaths

Edgar Alphonso Hines * Seneca, S. C.; Medical College of the State of South Carolina, Charleston, 1891; member of the House of Delegates of the American Medical Association from 1910 to 1928 and from 1930 to 1940; vice chairman of the state board of health for many years and one of the founders of the board's bureau of child hygiene; past president of the South Carolina Pediatric Society and the Piedmont Postgraduate Clinical Assembly; member of the American Academy of Pediatrics; fellow of the American College of Physicians; in 1913, session chairman of the International Congress of School Hygiene in Buffalo; for many years trustee and chairman of the school board; on the staff of the Oconee County Hospital; superintendent of the Anderson County Hospital, Anderson, for 1915; secretary of the South Carolina Medical Association; secretary-treasurer of the Oconee County Medical Society; editor in chief of the *Journal of the South Carolina Medical Association*; chairman of the Committee on Medical Preparedness for South Carolina; aged 73; died, November 27, of coronary occlusion.

Philip King Brown * San Francisco; Harvard Medical School, Boston, 1893; assistant in nervous diseases, University of California Medical School in 1894, associate professor of clinical medicine from 1896 to 1898 and instructor of animal pathology from 1896 to 1899; associate in medicine and instructor of clinical pathology, Cooper Medical College from 1899 to 1902; member of the Association of American Physicians and the American Clinical and Climatological Association; served in various capacities and at various times on the staffs of the Southern Pacific Hospital, Stanford University Hospital and the City and County Hospital, San Francisco; secretary of the board of directors, founder and for many years medical director of the Arequipa Sanatorium, Manor; aged 71; died, October 29, of coronary thrombosis.

Lemuel Payson Adams * Oakland, Calif.; University of Vermont College of Medicine, Burlington, 1899; member of the House of Delegates of the American Medical Association in 1925; senior fellow of the Pacific Coast Surgical Association; a founder of the American Association for the Surgery of Trauma and of the American Board of Surgery; fellow of the American College of Surgeons; chief of the East surgical staff of the Alameda County Hospital, Oakland, and the Fairmount Hospital, San Leandro; a director and member of the staff of Peralta Hospital, Oakland; aged 65; died, October 27, of coronary embolism.

Jackson Thornwell Witherspoon * New York; Johns Hopkins University School of Medicine, Baltimore, 1928; member of the Indiana State Medical Association; formerly instructor and later assistant professor of gynecology at Tulane University of Louisiana School of Medicine, New Orleans, and assistant professor and subsequently associate professor of gynecology at the Indiana University School of Medicine, Indianapolis; author of "Clinical Pathological Gynecology"; at one time editor of *Modern Medicine*; aged 40; died, October 19, at his home in Darien, Conn.

John Henry Rishmiller * Gibbon, Minn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; past president of the American Association of Railway Surgeons; formerly chief surgeon of the Soo Line; at one time on the staff of the City Hospital and Swedish Hospital, Minneapolis; aged 74; died, October 15, of cerebral embolism, cerebral hemorrhage and essential hypertension.

George Robert Cruickshank, Windsor, Ont., Canada; Victoria University Medical Department, Coburg, 1886; L.R.C.P., Edinburgh, Scotland, 1890; past president of the College of Physicians and Surgeons of Ontario; member of the Senate of the University of Toronto for many years; medical officer of health for Windsor from 1914 to 1919, and helped to organize the present board of health; in 1919 was president of the Ontario Health Officers Association; aged 80; died, October 8.

Roland Beatty Tupper * Fresno, Calif.; Cooper Medical College, San Francisco, 1910; at one time assistant clinical professor of medicine at his alma mater; member of the American College of Chest Physicians; served during the World War; formerly on the staff of St. Luke's Hospital, San Francisco; aged 54; on the staffs of the Fresno General Hospital and the Burnett Sanitarium, where he died, October 30, of coronary occlusion.

Henry Edward Menage, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1892; member of the Louisiana State Medical Society and the American Academy of Dermatology and Syphilology; professor of dermatology emeritus at his alma mater; veteran of the Spanish-American War; formerly on the staff of the Charity Hospital; aged 68; died, October 22, of arteriosclerotic heart disease.

Samuel Jackson Pate, Woodville, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1905; member of the State Medical Association of Texas; past president of the Jefferson County Medical Society; served during the World War; on the staffs of the Hotel Dieu Hospital and St. Therese Hospital, Beaumont; aged 62; died, October 17, of chronic nephritis, myocarditis and hypertension.

Frederick Francis Andrews * Revere, Mass.; Harvard Medical School, Boston, 1905; for many years school physician; formerly member of the board of health; on the staffs of the Winthrop (Mass.) Community Hospital, Whidden Memorial Hospital, Everett, and the Chelsea (Mass.) Memorial Hospital; aged 68; died, November 5.

William A. Spurgeon, Muncie, Ind.; Physio-Medical College of Indiana, Indianapolis, 1875; member of the Indiana State Medical Association; past president of the Indiana State Board of Medical Registration and Examination and of the American Confederation of Reciprocating Medical Licensing Boards; aged 88; died, October 21.

Monroe T. Smith, Warren, Pa.; Medico-Chirurgical College of Philadelphia, 1889; member of the Medical Society of the State of Pennsylvania; past president of the Warren County Medical Society; for many years on the staff of the Warren General Hospital; aged 74; died, October 25, of coronary embolism.

Francis William Briggs * Havre, Mont.; State University of Iowa College of Medicine, Iowa City, 1905; member of the American Academy of Ophthalmology and Otolaryngology; on the staffs of the Sacred Heart and Deaconess hospitals; aged 66; died, October 27, in Great Falls, of heart disease.

Henry R. Krasnow, Chicago; Chicago College of Medicine and Surgery, 1914; instructor of dermatology at the University of Illinois College of Medicine; aged 57; on the staffs of the Research and Educational Hospital and the American Hospital, where he died, October 31, of coronary thrombosis.

Raymond Braxton Kicklighter, Glennville, Ga.; University of Georgia Medical Department, Augusta, 1928; member of the Medical Association of Georgia; served during the World War; aged 46; died, October 29, in the Veterans Administration Facility, Oteen, N. C., of tuberculosis.

Florence Gertrude Mikulski, Buffalo; University of Buffalo School of Medicine, 1924; member of the Medical Society of the State of New York and the American Society of Anesthetists; on the staffs of the Millard Fillmore and Lafayette General hospitals; aged 46; died, October 24.

Earle Haggett MacMichael, Englewood, Fla.; Harvard Medical School, Boston, 1910; served during the World War; member of the New England Society of Psychiatry; aged 56; died, October 27, in Venice of hypertensive heart disease, arteriosclerosis and arthritis deformans.

George J. Hess, Wayne, Neb.; Detroit College of Medicine, 1894; member of the Nebraska State Medical Association; also a pharmacist; president of the Wayne County Medical Society; aged 72; died, October 25, in a hospital at Norfolk of cerebral hemorrhage.

Clinton C. Tyrrell, Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1906; member of the Minnesota State Medical Association; served during the World War; aged 63; died, October 22, of chronic myocarditis and arteriosclerosis.

John Gilmer Reynolds, Chatham, Va.; Hospital College of Medicine, Louisville, Ky., 1904; member of the Medical Society of Virginia; aged 71; died, October 25, in the Memorial Hospital, Danville, of arteriosclerosis, myocarditis and bronchopneumonia.

Eb Nichols Gray, Houston, Texas; Jefferson Medical College of Philadelphia, 1883; member of the State Medical Association of Texas; on the staffs of the Memorial, Hermann and Jefferson Davis hospitals and St. Joseph's Infirmary; aged 79; died, October 19.

Charles Sumner Reed, Agency, Iowa; Drake University Medical Department, Des Moines, 1902; member of the Iowa

State Medical Society; past president of the Wapello County Medical Society; aged 70; died, October 4, of cerebral hemorrhage.

Preston Winford Pearson, Emory, Texas; Memphis (Tenn.) Hospital Medical College, 1903; member of the State Medical Association of Texas; past president of the Hunt-Rockwell-Rains Counties Medical Society; aged 57; died, October 12.

Wilbur Moate Scott * Milledgeville, Ga.; University of Maryland School of Medicine, Baltimore, 1912; served during the World War; member of the Southeastern Surgical Congress; owner of the Scott Hospital; aged 49; was found dead, October 31.

William Bedwell Harrell Sr., Thomaston, Ala.; Louisville (Ky.) Medical College, 1905; member of the Medical Association of the State of Alabama; aged 59; died in October at a hospital in Birmingham of a severed artery, self inflicted.

William Alonzo Smith, Panther Burn, Miss.; Memphis (Tenn.) Hospital Medical College, 1912; member of the Mississippi State Medical Association; aged 57; died, October 6, in the King's Daughters' Hospital, Greenville, of pneumonia.

James Harvey Hudson, Merrill, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883; formerly member of the school board, mayor and postmaster; aged 81; died, October 24, of multiple sclerosis.

Edwin Cornue Hoff * Detroit; Cleveland Homeopathic Medical College, 1901; fellow of the American College of Surgeons; aged 65; on the staff of the Grace Hospital where he died, October 23, of heart disease and prostatectomy.

Walter Wesley Sawyer, Elizabeth City, N. C.; University of Maryland School of Medicine, Baltimore, 1903; member of the Medical Society of the State of North Carolina; aged 60; died, October 20, of coronary thrombosis.

Nathan I. Kithcart, Columbia City, Ind.; Medical College of Ohio, Cincinnati, 1881; member of the Indiana State Medical Association; formerly secretary of the Whitley County Medical Society; aged 89; died, October 29, of myocarditis.

Albert Earl Sumner, Richmond Hill, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1894; consulting physician to the Roosevelt Hospital, New York; aged 73; died, October 31.

Owen F. Moran, Milledgeville, Ga.; Atlanta Medical College, 1888; member of the Medical Association of Georgia; formerly county commissioner of health; aged 73; died, October 31, of myocarditis and arteriosclerosis.

Francis Joseph Noonan, Troy, N. Y.; Albany Medical College, 1905; served during the World War; on the staff of the Troy Hospital; aged 59; died, October 18, of cerebral hemorrhage, arteriosclerosis and diabetes mellitus.

Bert Luther Kennedy, Dalton, Ga.; Birmingham (Ala.) Medical College, 1911; member of the Medical Association of Georgia; aged 59; died, October 17, in the Newell Sanitarium, Chattanooga, Tenn., of coronary occlusion.

John H. Heidelman, Ronan, Mont.; Cincinnati College of Medicine and Surgery, 1891; formerly a member of the Indian Service; aged 74; died, September 29, at the St. Patrick Hospital, Missoula, of coronary occlusion.

Melvin D. Hereford * Staten Island, N. Y.; University of Kansas School of Medicine, Kansas City, Kan., 1922; served during the World War; on the staff of the Richmond Memorial Hospital; aged 43; died, October 25.

Henry Learen Applewhite, Archer City, Texas; Southern Methodist University Medical Department, Dallas, 1914; member of the State Medical Association of Texas; aged 53; died, September 6, in a hospital at Olney.

James P. Womack, Nashville, Tenn.; University of Tennessee Medical Department, Nashville, 1886; assistant to the chair in physiology at his alma mater, 1890-1891; aged 79; died, October 28, of cerebral hemorrhage.

Francis Joseph Harrington, Fall River, Mass.; Maryland College of Eclectic Medicine and Surgery, Baltimore, 1914; aged 47; was found dead, October 14, of heart disease and chronic dilatation of the esophagus.

William Armine Humphrey, Columbus, Ohio; Hahnemann Medical College and Hospital, Chicago, 1883; fellow of the American College of Surgeons; aged 80; died, October 30, of arteriosclerotic heart disease.

Horace Hampton Hilliard, Canton, Texas; Baylor University College of Medicine, Dallas, 1917; member of the State Medical Association of Texas; served during the World War; aged 50; died, October 14.

Harry Willard Waterous, Galva, Ill.; Rush Medical College, Chicago, 1885; member of the Illinois State Medical Society; aged 81; died, October 24, in East Pepperell, Mass., of coronary occlusion.

Bernard Weiss * South Ozone Park, N. Y.; Long Island College Hospital, Brooklyn, 1929; on the staff of the Queens General Hospital, Jamaica; aged 36; died, October 20, of coronary thrombosis.

Arthur Wallace Winch, Sanford, Maine; Baltimore Medical College, 1906; served during the World War; aged 61; died, October 13, in the Deaconess Hospital, Boston, of pulmonary tuberculosis.

Victor Hugo Miller, Lakeland, Fla.; University of Louisville (Ky.) Medical Department, 1912; served during the World War; aged 53; died, October 16, in the Morrell Hospital of coronary thrombosis.

William Orville Wilkes, Waco, Texas; University Medical College of Kansas City, Mo., 1885; member of the State Medical Association of Texas; aged 77; died, October 17, of coronary sclerosis.

Roscoe Wesley Swan, Worcester, Mass.; Harvard Medical School, Boston, 1882; member of the Massachusetts Medical Society; aged 80; died, October 13, in the Holden (Mass.) District Hospital.

George Jackson Hill, Boston; Harvard Medical School, Boston, 1903; member of the Massachusetts Medical Society; formerly on the staff of the Children's Hospital; aged 61; died, October 29.

John Paul Hiebert * Minneapolis; Northwestern University Medical School, Chicago, 1905; on the staffs of the Eitel, Abbott and Asbury hospitals; aged 63; died, October 11, of carcinoma of the pancreas.

John T. Iles, Ewing, Texas; University of Arkansas School of Medicine, Little Rock, 1911; aged 63; died, October 16, in the Angelina County Hospital, Lufkin, of cardiovascular renal disease.

Joseph O. King, Ridge, Md.; Baltimore University School of Medicine, 1895; member of the Medical and Chirurgical Faculty of Maryland; aged 67; died, October 31, of pulmonary tuberculosis.

Charlotte Margaretha Sekler Koester, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; aged 69; died, October 2, of pancreatitis.

Kary Gibbon Parker * Mansfield, Ohio; Miami Medical College, Cincinnati, 1903; for many years on the staff of the Ohio State Reformatory; aged 65; died, October 24, of pneumonia.

John Roscoe Varney, Old Town, Maine; Baltimore Medical College, 1896; member of the Maine Medical Association; aged 77; died, October 25, of arteriosclerosis and pulmonary infarction.

Lloyd Thomas Reed, Gravity, Iowa; St. Louis College of Physicians and Surgeons, 1900; member of the Iowa State Medical Society; aged 62; died, October 17, of coronary occlusion.

Isaac H. Treece, Findlay, Ohio; Eclectic Medical Institute, Cincinnati, 1887; aged 77; died, October 24, in the Findlay Hospital of a wound received when his gun accidentally exploded.

Abraham Lincoln Trevaskis, Turtle Creek, Pa.; Starling Medical College, Columbus, 1892; member of the Medical Society of the State of Pennsylvania; aged 80; died, October 28.

Henry H. Clark, Minneapolis; College of Physicians and Surgeons of Chicago, 1893; member of the Minnesota State Medical Association; aged 76; died, October 31, of carcinoma-tosis.

Charles Joel Sage * New York; University of Vermont College of Medicine, Burlington, 1931; aged 36; died, October 18, in the Mount Sinai Hospital of acute myelogenous leukemia.

Jonas Ruby, Chicago; Chicago College of Medicine and Surgery, 1917; for many years school health officer; aged 54; died, October 21, in the American Hospital of coronary occlusion.

James D. Stuart, Washington, D. C.; Columbia University Medical Department, Washington, 1892; member of the Medical Society of the District of Columbia; aged 75; died, October 18.

Moses James Ferguson, Mexico, D. F., Mexico; University of Nashville (Tenn.) Medical Department, 1905; aged 58; died in October of injuries received in an automobile accident.

George A. Noon, Listie, Pa.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1890; member of the Medical Society of the State of Pennsylvania; aged 81; died, October 12.

Albert Sidney Stemler, Washington C. H., Ohio; Eclectic Medical Institute, Cincinnati, 1898; member of the Ohio State Medical Association; aged 66; died in October in Cleveland.

Willie Gregor Spires, Gaskin, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1916; formerly member of the county school board; aged 55; died, October 19.

Jesse Braxton Higgins, Indianapolis; Fort Wayne (Ind.) College of Medicine, 1901; aged 62; died, October 27, in the Veterans Administration Facility of coronary disease.

Frank Horan Gunn, Eau Claire, Wis.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1895; aged 68; died, October 13, of arteriosclerotic heart disease.

Napoleon J. Caron, South Hero, Vt.; Laval University Faculty of Medicine, Quebec, Canada, 1899; aged 69; died, October 23, of carcinoma of the lungs with metastasis.

John Walter Hertridge Jr., St. Louis; Meharry Medical College of Walden University, Nashville, Tenn., 1938; aged 28; died, October 6, of pulmonary tuberculosis.

Lloyd Howe Mott, Los Angeles (licensed in Oregon in 1912); on the staff of the Veterans Administration Facility, West Los Angeles; aged 53; died in October.

George E. French Ⓢ Elyria, Ohio; Western Reserve University Medical Department, Cleveland, 1888; for many years city health officer; aged 76; died, October 30.

William M. Van Der Volgen, Seattle; Kentucky School of Medicine, Louisville, 1877; Medical College of Ohio, Cincinnati, 1887; aged 84; died in October.

Reginald Myron Wildish Ⓢ Webster City, Iowa; University of Nebraska College of Medicine, Omaha, 1911; aged 55; died, September 30, of cardiac embolism.

William James Pillsbury, Baltimore; University of Maryland School of Medicine, Baltimore, 1889; aged 72; died, October 29, of cerebral hemorrhage.

Henry Andrew Life Ⓢ Harlingen, Texas; Barnes Medical College, St. Louis, 1899; aged 66; died, October 21, in the Masonic Hospital, Cherokee, Okla.

Lawrence Henry Oliver, Waupun, Wis.; Marquette University School of Medicine, Milwaukee, 1916; aged 54; died, October 30, of coronary occlusion.

George Tapscott Snead, Pungo, Va.; Medical College of Virginia, Richmond, 1880; formerly member of the state legislature; aged 83; died, October 30.

Walter A. Jenkins, Church Point, La.; Louisville (Ky.) Medical College, 1887; aged 80; died, October 15, of diabetes mellitus, nephritis and myocarditis.

Spencer De Witt Guy Ⓢ Lansing, Mich.; Rush Medical College, Chicago, 1917; served during the World War; aged 47; died, October 26, of pellagra.

Edwin B. Boots Ⓢ Terre Haute, Ind.; Indiana University School of Medicine, Indianapolis, 1930; aged 40; died, October 7, of a gunshot wound.

George Henry Belding, Milwaukee; Milwaukee Medical College, 1903; formerly a dentist; aged 77; died, September 15, of chronic endocarditis.

Alexander Neil MacLeod, Winnipeg, Man., Canada; Manitoba Medical College, Winnipeg, 1893; aged 72; died, October 11, of cerebral hemorrhage.

William McKee Thome, Salem, Ore.; Jefferson Medical College of Philadelphia, 1897; aged 71; died, October 22, of carcinoma of the prostate.

Isabella Holdom, Minneapolis; Michigan College of Medicine and Surgery, Detroit, 1897; aged 81; died, October 23, of cardiac decompensation.

John Earle Jenner, Vancouver, B. C., Canada; Trinity Medical College, Toronto, 1883; L.R.C.P., London, 1883; aged 83; died, October 28.

William Herbert Marshall, Weiser, Idaho; Trinity Medical College, Toronto, Ont., Canada, 1899; aged 66; died, October 18, in Boise.

Thomas Benjamin Smith, Bracey, Va.; Jefferson Medical College of Philadelphia, 1881; aged 81; died, October 15, of cerebral hemorrhage.

George L. Shoemaker, Jennings, La.; Chicago Homeopathic Medical College, 1891; aged 80; died, October 21, of coronary thrombosis.

William Henry Loechner, Omaha; Omaha Medical College, 1901; aged 63; died, October 28, of carcinoma of the head of the pancreas.

Charles Huston Minor, New York; Ohio State University College of Homeopathic Medicine, Columbus, 1920; aged 46; died, September 25.

Samuel S. Guerrant, Callaway, Va.; Medical Department of Tulane University of Louisiana, New Orleans, 1891; aged 73; died, October 28.

Morgan Biddle Jennings, Streator, Ill.; Rush Medical College, Chicago, 1886; aged 77; died, November 16, in St. Mary's Hospital.

James Thompson Longest, Pontotoc, Miss.; University of Tennessee Medical Department, Nashville, 1903; aged 68; died, October 24.

Howard Cousins Fairbanks Ⓢ Tonawanda, N. Y.; University of Buffalo School of Medicine, 1909; aged 54; died, October 13.

Alvin Dennett Holmes, Hudson, Mass.; Medical School of Maine, Portland, 1883; aged 84; died, October 24, of chronic myocarditis.

Walter Jay Insley, Columbus, Ohio; Bennett College of Eclectic Medicine and Surgery, Chicago, 1887; aged 83; died, October 26.

Walter Bryant Guy, St. Augustine, Fla.; Boston University School of Medicine, 1899; aged 70; died, October 3, of coronary thrombosis.

William James Brown, Boston; Tufts College Medical School, Boston, 1906; aged 60; died, September 15, in Plymouth.

Walter A. Gatlin, Paris, Texas; Memphis (Tenn.) Hospital Medical College, 1902; aged 67; died, October 25, of coronary occlusion.

Richard W. Carter, Chicago; Fort Wayne (Ind.) College of Medicine, 1893; aged 70; died, October 25, of chronic myocarditis.

Archibald M. McKennon, Clarksville, Ark.; Jefferson Medical College of Philadelphia, 1874; aged 88; died, October 23.

Francis Edward Carroll, Boston; Harvard Medical School, Boston, 1890; aged 78; died, September 10, in Saugus.

William Douglas Swan, Hamilton, Ont.; University of Toronto Faculty of Medicine, 1921; aged 50; died, October 23.

Alexander Douglas Taylor, Daytona Beach, Fla.; Rush Medical College, Chicago, 1875; aged 86; died, October 5.

Andrew J. Hays, Weslaco, Texas; Keokuk (Iowa) Medical College, 1891; aged 79; died, October 15, of myocarditis.

William Tecumseh Pittman, Spickard, Mo.; Rush Medical College, Chicago, 1892; aged 70; died, October 31.

Joseph A. Roth, Chicago; Harvey Medical College, Chicago, 1905; aged 66; died, October 14, of diabetes mellitus.

Eugene Clair Wasson, Cambridge Springs, Pa.; Baltimore Medical College, 1905; aged 62; died, October 19.

Thomas Z. Clower, Moreland, Ga.; Southern Medical College, Atlanta, 1893; aged 70; died, October 5.

George William May Ⓢ Manchester, Conn.; Milwaukee Medical College, 1895; aged 80; died, October 23.

James Griffin Elrod, Dutton, Ala.; Chattanooga (Tenn.) Medical College, 1902; aged 82; died, October 29.

Victoria Sarah Ernst, Bridgewater, N. S., Canada; Halifax Medical College, 1900; aged 84; died, October 4.

Joseph Ira Esch, La Farge, Wis.; Eclectic Medical Institute, Cincinnati, 1898; aged 71; died in October.

CORRECTION

Dr. Pearson Is Not Dead.—The obituary notice of Dr. Charles Birdsall Pearson of Anaheim, Calif., which appeared in *THE JOURNAL*, November 30, page 1905, was erroneous. Our source of information was a clipping from the *Grand Blanc, Mich., Press*, dated Oct. 10, 1940.

Correspondence

THE EFFECT OF ALCOHOL ON DRIVING SKILL

To the Editor:—The recent article "The Effect of Alcohol on Driving Skill" (*THE JOURNAL*, November 9, p. 1600) brings out a number of interesting facts but may lead to erroneous conclusions if not carefully scrutinized. An ingenious test of driving skill, including both steering and braking, showed that the two skills were more closely correlated than either or both with the exact concentration of alcohol in the blood stream. However, it should be noted that the subjects showed a remarkably similar concentration of alcohol in the blood after the test dose, in no instance varying by more than 0.03 per cent from the average concentration to be expected (chart 1) and almost all lying in the zone characterized by the committees of the American Medical Association and the National Safety Council, as well as most students of the subject, as of "suggestive" or "presumptive" rather than of "conclusive" or "prima facie" significance. Even in this narrow zone, the coefficient of correlation of 0.485, more than six times its probable error, is impressive. If the data had extended over the higher ranges, in which the chemical test is conclusive, as well as over the lower ranges, in which it distinguishes so usefully between the "had been drinking" and the "under the influence" group, a much higher degree of correlation would have undoubtedly appeared. As a matter of fact, the only four persons shown in chart 2 with sufficient alcoholic concentration in the blood to have been convicted by the chemical test alone all showed more than 15 per cent loss of efficiency in driving ability by the tests here reported.

The tests used appear to have been well calculated to bring out differences in driving skill, resulting from changes in reaction time and neuromuscular coordination. As emphasized in the preliminary report of the committee of the American Medical Association on this subject, the early effects of alcohol which may lead to automobile accidents are rather in the sphere of judgment, discretion and disposition than of the more mechanical skills here tested. The slightly intoxicated expert chauffeur may be much better able than the sober occasional driver to pass tests in steering and braking abilities but may also be more apt to take chances or be careless when not consciously being tested. The subject's fallacious impression that skill is improved during the influence of alcohol, noted here as in previous studies, also leads to greater dangers.

The contention that the chemical tests for intoxication penalize the drinking rather than the drunken driver is just the reverse of the facts. It is just the finding that a driver who has been drinking but has less than 0.05 per cent of alcohol in the blood generally fails to show other evidences of intoxication, while the one with more than 0.15 per cent may be shown to be under the influence if sufficiently examined, which makes this test of differential value, as compared with merely smelling the breath or showing the bottle.

It is still conceivable that a person might be found who can have a concentration of alcohol in the blood stream above 0.15 per cent and still fail to show any evidence of the effect of the alcohol on the tissues. Despite thousands of tests, however, and public appeals for the discovery of such person, no such instance has yet been verified. The search should be continued, as further study of such a case might be of great value for our understanding of the nature of tolerance to alcohol. Its occurrence, however, is still unproved.

If one disregards their comments and conclusions, the work of Newman and Fletcher may be accepted as a valuable contribution toward the evaluation of the status of the "borderline case" of the driver with a concentration of alcohol between 0.05

and 0.15 per cent. Practically every worker in this field, as well as the committees of the American Medical Association and the National Safety Council, have urged the use of other evidence in addition to, and in support of, the value of the chemical test, and the performance of the latter in duplicate, or with different samples, in questionable cases. The possibility of technical errors in the performance of the tests, as well as still unknown possibilities in their interpretation, should not be overlooked. The article on false positive serologic tests for syphilis in *THE JOURNAL* just following the paper by Newman and Fletcher, however, indicates how a similar valuable test in another field in medicine may be safeguarded rather than ignored. Further studies of tolerance to alcohol and the factors involved in automobile accidents are still greatly to be desired. At present, however, it may be emphatically reiterated that the determination of the alcoholic concentration of the breath or body fluids remains the most reliable single factor in arriving at a correct conclusion as to the degree of intoxication.

EMIL BOGEN, M.D., Olive View, Calif.

To the Editor:—The recent paper on "The Effect of Alcohol on Driving Skill" by Newman and Fletcher (*THE JOURNAL*, November 9, p. 1600) presents conclusions which are at variance with the majority of scientific investigations on the effects of alcohol. Their report demonstrates the extreme confusion which may result from varying conceptions of the terms "drunk" and "intoxicated." Some writers have maintained that any demonstrable deviation from normal behavior produced by alcohol constitutes alcoholic intoxication. By such a rigid definition most persons may be considered intoxicated following exceedingly small amounts of alcohol such as are contained in a single cocktail or "highball." The opposite extreme is indicated by the criterion often employed by bartenders in determining whether or not a customer may legally be sold further quantities of liquor. This view is perhaps best illustrated by the old barroom quatrain:

He is *not* drunk who from the floor
Can rise again and drink once more.
But he is drunk who prostrate lies
And can neither drink nor rise.

There is a world of difference between these two extremes in defining the term "drunk." When Newman and Fletcher state "Public sentiment is definitely against the drunken driver but not against the drinking driver," all can agree with them in principle. The really important question which must be answered is When does a drinking driver become a drunken driver? Certainly it is long before he reaches the staggering stage of alcoholic intoxication. As was suggested in *THE JOURNAL* ("The Subintoxicated Driver," May 2, 1936, p. 1580) four years ago, serious impairment of driving ability occurs before the ordinary indications of "intoxication" are observable; hence the use of the term "subintoxicated driver." The public associates the term "drunk" with a stage of alcoholic intoxication characterized by staggering gait and confused or slurred speech. Apparently on such a basis Jetter (cited by Newman and Fletcher in support of their thesis) made his clinical diagnosis of acute alcoholic intoxication. Such standards, while entirely suitable for purposes of hospital classification, are hardly adequate for diagnosis of the influence of alcohol on motorists.

The use of the term "under the influence of alcohol" seems to avoid the many deep-seated connotations which, through long usage, adhere to such words as "drunk" or "intoxicated." This condition might be defined as that state at which the effect of alcohol renders a person unfit to perform the particular task which he is attempting. To evaluate fairly the influence of alcohol requires one to take into consideration not only the effects of the alcohol which is circulating through

the body of that person but also the type of activity in which he is engaged. Thus a man may have taken several "high-balls" and seated himself in his home to listen to a radio program. For such a purpose he might be considered to be entirely sober. But if this same man were to undertake a task involving quick and accurate response to stimuli and the use of sound judgment, such as driving a high powered automobile through crowded city streets, he would be fairly classified as "under the influence of alcohol." The loose use of the terms "drunk" and "intoxicated" gives rise to much unnecessary confusion.

The psychologic tests of driving skill reported by Newman and Fletcher illustrate the difficulty in setting up an experimental routine which will measure the desired variable to the exclusion of all others. With reference to tests on the influence of alcohol, these difficulties have been admirably stated by Jellinek and McFarland (*Analysis of Psychological Experiments on the Effects of Alcohol, Quart. J. Studies on Alcohol* 1:272 [Sept.] 1940). Apparently what Newman and Fletcher have measured was impairment of driving skill due to the effect of alcohol plus improvement due to practice. Little wonder, therefore, that they find such poor correlation between alcohol concentration in the blood and their "loss of driving skill." The most eloquent practical demonstration of the correlation between alcohol content of body fluids and driving skill is to be found in the Evanston survey (Holcomb, R. L.: *Alcohol in Relation to Traffic Accidents, THE JOURNAL*, Sept. 17, 1938, p. 1076). A statistical study of the data was made to determine a motorist's chances of finding himself in an Evanston hospital following an automobile accident. Depending on the concentration of alcohol in the blood stream, these probabilities were as follows:

Alcohol in Blood, per Cent	Chances of Hospitalization Following an Automobile Accident
0	1
Less than 0.07.....	3
0.07 to 0.11.....	5
0.11 to 0.15.....	15
Over 0.15	55

It is not reasonable to expect perfect correlation between the dose of any drug and the effect which it produces (Nelson, E. E.: *Variability in Response to Drugs, THE JOURNAL*, Oct. 7, 1939, p. 1373). However, within the limits of normal biologic variation which my experience has indicated to be about 10 to 15 per cent in the case of alcohol (McNally, W. D.: *Toxicology, Chicago, Industrial Medicine*, 1937, p. 659), all persons, regardless of previous experience in the use of alcohol, are equally under the influence of alcohol when they have the same concentration of alcohol in their circulating blood. That determinations of alcohol in the blood leave much to be desired cannot be denied. However, they do serve as an excellent adjunct in the correct interpretation of less quantitative clinical indications of the influence of alcohol. Until better practical and more reliable methods can be found, one may safely continue to employ the methods recommended by the American Medical Association Committee to Study Motor Vehicle Accidents (*THE JOURNAL*, May 27, 1939, p. 2165) and embodied in the National Safety Council's program for safe driving practice.

The use of our highways is not an inherent individual right such as the rights of free speech, free assembly and freedom of worship. It is a privilege conferred by the communities in which we live and may be legally abridged in any way which seems in the interest of public safety and welfare. Society must be free to take effective steps in controlling the ever mounting toll of deaths and injuries due to highway accidents.

C. W. MUEHLBERGER, PH.D., Chicago.

Coroner's Toxicologist, Cook County
Coroner's Laboratory.

To the Editor:—In the article by Newman and Fletcher, "The Effect of Alcohol on Driving Skill" (*THE JOURNAL*, Nov. 9, 1940, p. 1600), are certain discrepancies which might not be perceived.

The authors give experimental data which apparently justify their attack on the "injustice" of the figure of 0.15 per cent alcohol in the blood, which has been set by committees of both the American Medical Association and the National Safety Council as the point at which 100 per cent of persons "tolerant" or otherwise suffer a definite impairment in their driving ability, to the extent that it comes within the meaning of most state laws concerning drunken driving.

They state that the purpose of their experimental work was to investigate the correlation between impairment of driving ability and the 0.15 per cent concentration of alcohol in the blood. Their data of ninety-eight trials on 65 subjects are presented in the form of a pinpoint chart percentage of impairment over normal performance against concentrations of alcohol in the blood. They say that it shows a poor correlation between the two. It does just that and nothing more. The validity of the recommended figure of 0.15 per cent remains unaffected, for the following reasons:

1. Eighty results were between approximately 0.06 and 0.12 per cent, nine between 0.12 and 0.14 per cent, one close to 0.15 per cent and three above 0.15 per cent. The majority of their results were therefore obtained at concentrations much below 0.15 per cent. The four at or above 0.15 per cent prove nothing.

2. The fifteen minute trial periods preceding the actual tests were totally inadequate to eliminate any progressive improvement from this factor. A fifteen minute trial could not possibly have resulted in a plateau of performance for each subject.

3. It is a well known fact that many persons with alcohol concentrations of the blood below 0.15 per cent have a degree of unaffected will power which they can summon to their aid, if there is a reason for them to do so, to compensate to a considerable degree for the effect of the alcohol. This factor in itself may reasonably be held accountable for the poor correlation that the authors found. It is difficult to avoid this compensatory effect in any study which involves performance observation at low concentrations of alcohol. The subject cannot help but be aware that he is expected to make as good a showing as he can. At these low concentrations the occasional unquestionable better performance in such tests is in my opinion due entirely to a compensatory effort over and above that needed to counteract the alcohol. The subject gives a better performance not because of any bettering effect of the alcohol but in spite of it.

It is my sincere belief, based on nearly four years of observing and running blood and urine alcohol tests on actual drunken drivers to a total of between 300 and 400 that, if by some unattainable means every drunken driver's physical condition could be observed unknown to him, no disagreements between concentrations and effects would ever be observed. One sees practically perfect agreements at higher concentrations, because in practically all persons this mechanism then either no longer functions or it is not powerful enough to overcome all the effects of the alcohol.

Whether this occasional exhibition of compensatory mechanism, fairly frequent at low concentrations but becoming rare at higher ones, is due to a progressive loss in will power (apace with progressive impairment in other functions), to a variability in the development of individual will power or to a complex interplay of the two is difficult to say. The important point to keep in mind is that intoxicated persons do not make any effort to exert this compensatory mechanism while driving a car. It never occurs until the person is arrested and is under observa-

tion for his condition. One must remember that, in the ultimate analysis, blood and urine tests are made to determine the stage of intoxication of the subject while he was driving a car and not necessarily after various extraneous factors which unavoidably follow his arrest have entered the picture. These factors are well known to be able to modify the relation between the concentration of alcohol in the blood and the observable effect.

No one has yet succeeded in devising an apparatus to be used in the laboratory in testing driving ability which will take into account all factors, including judgment and estimation of risks, which play a part in determining what an intoxicated person will do, or fails to do, when behind the wheel of a car.

Up to now in only one known instance in the United States has such a study been made wherein the subjects actually drove a car. This was reported in the *Pennsylvania Medical Journal* for December 1932 by Drs. H. A. Heise, Benjamin Halporn and Alfred G. Dietze. The results were considerably different than those of Dr. Newman and Mr. Fletcher. In Dresden, Germany (*THE JOURNAL*, May 7, 1938, p. 1617), a series of tests were made on a large number of volunteers. At a concentration of 100 mg. of alcohol per hundred cubic centimeters of blood, there were 87 per cent of the drivers incapacitated and at 140 mg. 100 per cent.

Newman and Fletcher should repeat their experiment and see to it that the following points are observed: 1. Their subjects should be given doses of alcohol large enough to insure their blood alcohol being at or slightly above 0.15 per cent. 2. Care should be taken that the factor of compensation is eliminated as much as possible by using other than medical students and physicians as subjects and avoiding any hint to the subject, intentional or otherwise, that he is expected to try to drive better because of the alcohol. No suggestion (such as that of a signaling green light) should be given the subject that his alinement of radiator cap with the truck is faulty other than that given by his own judgment. 3. A longer practice period should be given and a plateau definitely established before the alcohol is administered. If this is done, my opinion is that Dr. Newman will obtain a considerably different result.

D. F. DAVIS,

City Health Department, Lincoln, Neb.

To the Editor:—The article "The Effect of Alcohol on Driving Skill" by Newman and Fletcher (*THE JOURNAL*, November 9, p. 1600), questions the value of chemical tests for intoxication. This paper demands an answer, since the conclusions of the authors are warranted neither from their own experimental data nor from their interpretation of the writings of others.

The authors direct their attack particularly to the recommendations of the Committee on Tests for Intoxication of the National Safety Council, and incidentally to the 1939 Report of the Committee of the American Medical Association for the Study of Problems of Motor Vehicle Accidents. These committees have agreed that certain levels of alcohol in the blood or their equivalents in other body fluids are associated with a definite loss of that clearness of intellect and self control which an individual would normally possess. Although the committees realize that there is no minimal figure that can be set at which there will be no effect from alcohol, they agree that all persons are definitely inferior to their normal capabilities when the alcohol concentration exceeds 0.15 per cent. (To reach a blood alcohol concentration of 0.15 per cent, the average sized adult must fail to oxidize from 3 to 4 ounces [90 to 120 cc.] of absolute alcohol.)

The reason for the disagreement is obviously the failure of Newman and Fletcher to realize that there is a vast difference

between the poorly defined terms of *drunkenness* and *intoxication*, and the well defined "under the influence of alcohol."

The National Safety Council Committee recommends that trial courts adopt the definition of the phrase "under the influence of alcohol" as laid down by the Supreme Court of Arizona:

"The expression 'under the influence of intoxicating liquor' covers not only all the well known and easily recognized conditions and degrees of intoxication but any abnormal mental or physical condition which is the result of indulging in any degree in intoxicating liquors, and which tends to deprive him of that clearness of intellect and control of himself which he would otherwise possess. If the ability of the driver of an automobile has been lessened in the slightest degree by the use of intoxicating liquors, then the driver is deemed to be under the influence of intoxicating liquor. The mere fact that the driver has taken a drink does not place him under the ban of the statute unless such drink has some influence upon him lessening in some degree his ability to handle said automobile."—*Steffani v. State*, 42 Pac. (2nd) 615.

The fact that a skilled driver under the influence of alcohol may be able to drive better than an ordinary sober person does not in any way clash with the definition.

The published results of the authors' experiments, involving the use of a machine which measures steering ability and reaction time, do not refute the conclusions of the committees of the American Medical Association and National Safety Council. On the contrary, the four persons whose blood alcohol concentrations exceeded 0.15 per cent all showed 16 per cent or more loss of efficiency, which would definitely place them "under the influence."

The authors state that performance of their test of simple steering is a better criterion of intoxication than is blood alcohol. My experiments along similar lines (*Medicolegal Aspects of Drunkenness*, *Pennsylvania M. J.* 36:190 [Dec.] 1932) but under actual driving conditions indicated that the ability to perform the routine of driving was not always obviously impaired in persons who were under the influence of alcohol according to chemical tests. However, the performances of acts which were not routine, such as backing the car and manipulations demanding judgment, were poorly performed. A simple incident is responsible for abandonment of this type of test: a truck swerved across the path of the test car, narrowly avoiding a collision. When I said to the driver, who at that time tested about 0.13 per cent, "Say, wasn't that a narrow escape from that truck?" he looked at me with an expressionless face, saying, "What truck?" After this incident, less dangerous experiments involving skill, judgment and intelligence were instituted. By these tests it was a simple matter to demonstrate definite impairment in judgment and personality long before coordination was affected. In all my experiments, involving more than 200 persons, no one was found who was able to reach a blood alcohol concentration of 0.10 per cent without showing definite changes for the worse.

The conclusions of the authors are not warranted from their interpretation of the writing of Bogen (*Drunkenness: A Quantitative Study of Acute Alcoholic Intoxication*, *THE JOURNAL*, Oct. 29, 1927, p. 1508), himself a member of the Committee on Tests for Intoxication of the National Safety Council. Bogen reports the cases of persons who were adjudged intoxicated or drunk and not persons who were proved to be "under the influence."

Jetter's subjects (*Studies in Alcohol*, *Am. J. M. Sc.* 196:475, 487 [Oct.] 1938) were adjudged intoxicated by a criterion which he himself set. In a recent article (*The Chemical and Clinical Diagnosis of Acute Alcoholism*, *New England J. Med.* 221:1019 [Dec. 28] 1939) he makes his position clear:

While only 50 per cent of cases in a group of habitual drinkers will be clinically intoxicated at a blood alcohol level of 0.15 Gm. per 100 cc., sufficient impairment of faculties will be present in even this type of individual to make him a menace as a driver.

Finally, I heartily disagree with the authors' implication that persons of greater skill than the average should not be penalized for their only offense of having alcohol in their blood stream. They would condone the resulting loss of driving

skill as long as the drivers managed to stay above "minimum standards of skill." They forget that the average driving skill results in a slaughter of more than 30,000 people in this country each year and that the superior driver has no legal or moral right to lower his efficiency toward the average.

HERMAN A. HEISE, M.D., Milwaukee.

Chairman, Committee of the American Medical Association to Study Problems of Motor Vehicle Accidents.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SERUM FOR POLIOMYELITIS

To the Editor:—What is the present status of convalescent serum in the treatment of anterior poliomyelitis?

J. G. Woodin, M.D., Grand Island, Neb.

ANSWER.—A simple and unchallenged answer cannot be given on the beneficial effect of convalescent serum in the treatment of acute anterior poliomyelitis. The reasons lie somewhat in the variability of the disease itself and, as in other acute infectious diseases, in the fact that the disease is self limiting. Although the early workers in this field were unanimous in stating that convalescent serum tended to prevent the spread of paralysis and aided in the recovery of paralysis, present day workers view this early opinion with skepticism. At present the matter is to be considered somewhat undecided but with the potential field of usefulness of serum markedly narrowed.

Reaction against the wholesale indiscriminate use of convalescent serum dates from the report of Park on the New York epidemic of 1931 (Therapeutic Use of Antipoliomyelitis Serum in Preparalytic Cases of Poliomyelitis, *THE JOURNAL*, Sept. 24, 1932, p. 1051; *New York State J. Med.* 33:91 [Jan. 15] 1933). This author reported on the serum treatment of half of the patients from a group of 927 in the preparalytic stage. The amount of paralysis judged by muscle examinations made shortly after the administration of serum and six months later showed no difference between the group that received serum and that which had received none. The data from this report were questioned by many workers in the field because alternate cases were not treated and serum was given to those seen late in the natural course of the preparalytic disease. It has since been shown that patients in the preparalytic stage, seen two or more days after the onset of paralysis, are already selected naturally and are destined to have little paralysis. The situation is further complicated by the fact that a large share of all cases diagnosable in the "preparalytic state" are actually nonparalytic cases; 71.5 per cent of 531 patients according to one published review (Harmon, P. H.: Poliomyelitis: Experimental and Theoretical Basis for Serum Therapy, *Am. J. Dis. Child.* 47:1179 [June] 1934). Harmon also failed to find statistical evidence for the beneficial use of convalescent serum. The incidence of paralysis and the apparent prevention of paralysis by serum were the same according to these statistics regardless of whether the serum used was convalescent serum, the antistreptococcus horse serum of Rosenow or "normal" human serum, which contains antiviral antibodies active in the test tube. Likewise, Kramer, Aycock, Solomon and Thenebe (Convalescent Serum Therapy in Preparalytic Poliomyelitis, *New England J. Med.* 206:432 [March 3] 1932) in the 1931 epidemic in Connecticut failed to find any difference in a control group of patients who did not receive convalescent serum and a similar group of patients who had received this agent.

The majority of workers have preferred to continue their observations. Convalescent serum admittedly does no harm and it has not yet been proved that it is valueless. Some favorable results have been recorded in recent years. Cowie, Parsons and Lowenberg have reported no residual paralysis in 80 preparalytic cases treated with both human convalescent serum and transfusions from "normal" adults. They also reported symptomatic improvement in certain paralytic cases. However, that serum was responsible solely for this turn of events must be viewed with skepticism in view of the well known tendency of

the disease to halt spontaneously and suddenly in the face of apparent advancing paralysis (Clinicopathologic Observations on Infantile Paralysis: Report of 125 Acute Cases with Special Reference to the Therapeutic Use of Convalescent and Adult Blood Transfusions, *Ann. Int. Med.* 8:521 [Nov.] 1934).

The most continuous experience with the use in convalescent serum in the treatment of this disease has been that of pediatricians and public health workers in the state of Illinois. The last official report originating from this source was that of Levinson (Poliomyelitis in the Chicago Area, *Illinois M. J.* 70:296 [Sept.] 1936). This author reported on the treatment of 149 preparalytic cases occurring in Chicago between 1931 and 1935. In the 1936 epidemic a mortality rate of 39 per cent was reported in bulbar cases (the mortality in untreated cases was 90 per cent). Only 8 patients from 53 preparalytic cases became paralyzed after serum was administered. The mortality in the latter group was zero and only 2 had slight residual paralysis. While the incidence of paralysis in this group of preparalytic cases was not dissimilar to those not receiving serum, it should be pointed out that the incidence of residual paralysis was practically zero. A recent report emanating from California (Geiger, J. C.; Burlingame, R. W., and Miller, R. C.: Convalescent Serum in Acute Anterior Poliomyelitis: Report of a Study of 168 Patients, 69 Treated, 98 Untreated, *California & West. Med.* 51:303 [Nov.] 1939) states that "the cases with entrance paralysis show little or no variation between treated and untreated in percentage in partial or complete recovery or death. Among those considered early cases, but with entrance weakness, the percentages of partial or complete recovery showed equally small or no variation in the treated and untreated. The early cases with no weakness or paralysis, however, indicate that a different viewpoint can be stressed. The preparalytic cases (27), when treated with convalescent serum, recovered without any residual paralysis. Therefore, in this series of cases of this type, or in early cases of acute anterior poliomyelitis with clinical and laboratory evidence substantiating the diagnosis, it would appear that convalescent serum is of benefit."

All the experimental evidence deduced from the use of convalescent human and monkey antiserum in the disease in monkeys clearly shows that the experimental disease is not benefited by serum. Such evidence should not be considered in evaluating the results in man, as the simian disease is entirely different in its onset, course and outcome. The disease in man is notoriously more variable and more mild both in extent of paralysis and in mortality.

The aggregate of opinion in recent years, as evidenced by the opinions and quotations given, would favor the use of human convalescent serum or transfusions from at least two or three normal adult blood donors during the preparalytic stage, while in cases of early paralysis in which the paralysis has ceased to advance and the temperature has dropped to normal serum should not be used. There are those who continue to use serum in early paralytic poliomyelitis, but no evidence can be said to favor such a procedure. From the practical point of view, it must be pointed out that the differentiation between preparalytic poliomyelitis and the early paralytic stages of this disease is exceedingly difficult.

LOCAL TREATMENT OF NASOPHARYNX IN "INFLUENZA"

To the Editor:—For the past two years I have noted a vesicular pharyngitis quite regularly in patients having the classic symptoms of influenza. This observation has been described as frequently accompanying the nasal pharyngitis that results from influenza. Is there any local treatment other than ephedrine shrinkage of the nasal pharynx and local application of silver salts that might be more specific as a remedy for the cough and gastrointestinal irritation that accompanies this lesion?

Henry E. Davidson, M.D., Lead, S. D.

ANSWER.—The use of weak ephedrine solutions in the nose by means of drops, use of an atomizer or following the recommendations of Proetz, is a useful method of treating the rhinitis and rhinopharyngitis following the so-called "flu." The vesicles, after they have ruptured, may be treated by the application of silver salts together with hot nonirritating gargles. To the extent that the reduction of nasal secretion prevents the cough which is due to purulent matter dropping into the larynx and trachea, the cough will be improved. That part of the cough which is due to a laryngotracheitis should be dealt with by the use of mixtures containing codeine, by steam inhalations, bed rest and the like.

The gastrointestinal irritation is probably not due to the local nose and throat condition but is a part of the general picture and has to be dealt with in a common sense manner. This calls for a proper bland diet, the avoidance of drastic cathartics and similar rational measures.

MEDICAL EXAMINATIONS OF FOOD HANDLERS

To the Editor:—Please advise me whether an examination of feces is desirable on food handlers in an institution where 1,700 young women eat in three large dining halls and where the following public health measures are carried out: complete examination of all food handlers, laborers and maids, including routine roentgen examinations of the chest, urinalysis and blood agglutination tests for typhoid, proteus, tularemia, abortus and the paratyphoid groups. We have never made any examination of stool specimens and accordingly I am asking your advice as to the advisability of this practice. We are anxious to take every precaution to insure the health of our people. I might add that the dishes are boiled under high pressure in all eating places, including all tea rooms about the campus, and that all food handlers have special instructions about cleansing hands, finger nails and their bodies in general.

William B. Brown, M.D., Columbia, Mo.

ANSWER.—In general, routine examination of food handlers in large numbers is an expensive procedure. A single stool examination gives little information. It is not unusual to have a number of negative stool cultures followed by a positive culture in the case of a typhoid carrier. In an institution where every possible protection is desired and, especially, if the turnover in employees is not great, routine examination of stools is of some value. The limitations of the possibilities of detecting cases or carriers from a single examination must be remembered, however. If there is a history of typhoid it is desirable that repeated stool cultures be made.

From the point of view of protection of those served by the employees, little could be expected of the agglutination tests for typhoid, proteus (typhus fever, Rocky Mountain spotted fever), tularemia, undulant fever and paratyphoid. With the exception of typhoid and paratyphoid fever, direct transmission from patient to patient either does not occur in these diseases or is an insignificant factor in their spread.

The agglutination test is of little value in the detection of typhoid carriers. Probably the education of food handlers is the most important disease prevention factor. Food handlers should have knowledge of the practical facts concerning the transmission of communicable diseases and should have medical attention available for the investigation of any signs of illness.

AMENORRHEA

To the Editor:—A white woman aged 26, married, weighing 106 pounds (48 Kg.) complains of small and poorly developed breasts. She says that they were well developed seven years ago. The menses began at 13, were regular every twenty-eight days and lasted five or six days. There was no dysmenorrhea. She had a miscarriage at three and one-half months eight years ago, an appendectomy seven years ago, a miscarriage at four and one-half months six years ago and a cholecystectomy three years ago. She has had amenorrhea since the last miscarriage six years ago. In 1937 she received two roentgen treatments over the pituitary followed by two regular menstrual periods. Physical examination revealed no abnormalities of the heart, the pulse is 80 and blood pressure 110 systolic, 65 diastolic. The abdomen shows the scar over the gallbladder area and midline below the umbilicus. The uterus is small but palpable. What procedure can be followed?

M.D., New Jersey.

ANSWER.—Unless the young woman is desirous of having children there is no reason to try to induce uterine bleeding. However, if there is a psychic disturbance because of the absence of menstruation, bleeding may be induced by so-called withdrawal therapy. A simple way to accomplish this is to administer 10,000 international units of estrone hypodermically three times a week for two weeks. Usually bleeding occurs about eight or ten days after the last injection. However, this form of therapy will produce only one bleeding episode. If the physician desires to produce cyclic bleeding he will have to repeat the series of injections every month.

If the patient is anxious to have a baby it is essential to find out whether the ovaries are functioning. Two things must be done. One is to obtain an endometrial biopsy at weekly intervals to see the type of endometrium which is present. If successive biopsies show a change from proliferative to secretory endometrium, this is evidence of the presence of ovulation. It is possible to have ovulation without menstruation and vice versa. If biopsies reveal secretory endometrium there is no need to give the patient treatment for the amenorrhea. Since she ovulates she can conceive.

If, on the other hand, the biopsies show persistent proliferative endometrium or hyperplasia the patient does not ovulate. In addition to endometrial biopsies a study of the urine should be made to determine the amount of gonadotropic hormone. If there is an excessive amount of this hormone it indicates that the ovaries are not functioning properly. An attempt may be made to stimulate ovulation by the administration of the gonadotropic substance obtained from pregnant mares' serum but the results have not been encouraging.

The amenorrhea may be overcome by radiation therapy of the pituitary gland. However, this treatment should be carried out only by a skilful roentgenologist.

The patient should have a basal metabolism study. If the rate is low, thyroid medication should be given, because not infrequently thyroid extract overcomes amenorrhea in women with hypothyroidism.

UNUSUAL PAIN AT CLOSE OF MENSTRUAL PERIOD

To the Editor:—A woman aged 21 with no physical defects and a perfectly normal menstrual history has severe pains starting at the end of each menstrual period. These pains are of the same type as tic douloureux; that is, a severe pain comes on lasting two minutes with complete relief for six or eight minutes, only to be repeated. They increase in severity until she is given a hypodermic of morphine one fourth grain (0.016 Gm.). The pain is to the right of the median line, apparently over the right ovary. There is absolutely no tenderness on deep pressure. Ordinary analgesics have no effect. The condition has been going on for years. No pelvic examination has been made. Can you give me any enlightenment on this case?

L. C. Howe, M.D., Muscatine, Iowa.

ANSWER.—This is a puzzling type of pain for which there does not seem to be any physiologic reason. Therefore it is difficult to recommend any therapy. Endocrine treatment will almost certainly be of no avail. If the patient is a virgin, a bimanual recto-abdominal examination should be made to rule out a possible pelvic lesion. Otherwise a vaginal examination should be made. If no abnormality is found, a pelvic sympathectomy may be justified because of the long duration of the pain and because of the strong likelihood of making the patient a morphine addict.

LATE FALL ASTHMA

To the Editor:—A woman, aged 26, living in midwestern Wisconsin, complains of asthma-like attacks of many years' duration. She states that the attacks start in the latter part of September. The condition is at its worst late in October. "As soon as the leaves are off the trees," as the patient states it, she feels all right. Please advise me what kind of agent could cause these attacks of asthma or hay fever. The physical examination revealed wheezing all over her chest.

M.D., Wisconsin.

ANSWER.—It is not uncommon to find patients who have asthma after the ragweed hay fever season is over. At this season one must think especially of corn smut or corn dust and of molds; perhaps the asthma coincides with fall house cleaning and the patient may be sensitive to house dust. Perhaps the patient may be allergic to fruits which are being preserved or she may be sensitive to foods eaten particularly at this season, e. g. grapes, pumpkin, plums and pears. It may be too that the dog or cat is invited into the house as cold weather sets in. In most cases careful history and thorough skin testing, both cutaneously and intracutaneously, will reveal sensitivity to one or more antigens.

ADDICTION TO AMPHETAMINE
(BENZEDRINE) SULFATE

To the Editor:—I wish to add my comments to the case reported on addiction to amphetamine (benzedrine) sulfate by Dr. L. J. Mahne in *Queries and Minor Notes*, November 2. First, his case is exceptional. I have used amphetamine (benzedrine) sulfate regularly in the treatment of alcoholism. I have run across no case in which the individual did not easily drop the drug after the desired results of prolonged abstinence from alcohol had been reached. The reason there have been no specific reports of cases of addiction to amphetamine sulfate is a simple one. Practically speaking, there are no such cases. In a continuous experience with the drug over the past four years I have not had one case which could be properly classified as drug addiction. True, there have been people who have suffered from chronic depression to whom the drug gave some degree of relief, who have continually used it during the period of time of treatment. However, they have not found it necessary to increase the dose in order to obtain the desired effect and, in fact, in the majority of cases the dosage has rarely been more than from one to one and one-half tablets a day, and in a considerable number of cases less than 10 mg. or one tablet a day has been sufficient. The psychologic effect is obtained more readily, I believe, with the smaller dose than the larger one. One might as well speak of the continued use of insulin by a diabetic patient as drug addiction. During the period of diabetes he has to take insulin steadily and continuously. When his disease recedes, so that diet alone is sufficient, he does not take insulin. The same situation prevails in the vast, almost overwhelming, majority of persons using amphetamine sulfate. Cases of sudden death have been recorded following the use of this drug but not beyond the range of mere coincidence. You cannot use any drug, including sterile saline solution, in a large number of cases without sudden death following an injection. If enough people with chronic or severe illness are treated with anything, death will ensue in some coincidental relationship. It is true that the drug should not be used when there is hypertension, gastrointestinal atony or profound excitement. Its use should be dropped immediately when good results do not follow quickly. Taking its total physiologic reactions into account and comparing it with other potent drugs, such as strychnine, atropine and digitalis, amphetamine sulfate is a relatively safe drug to use.

Abraham Myerson, M.D., Boston State Hospital,
Dorchester Center, Mass.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, December 14, page 2107.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 17-19. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: * Phoenix, Jan. 7. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: * *Eclectic*. Little Rock, June 5-6. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral examination* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, Jan. 29. *Written*. Los Angeles, Feb. 24-27. Sec., Dr. Charles B. Pinkham, 1020 N. St., Sacramento.

COLORADO: * Denver, Jan. 7-10. Applications must be on file not later than Dec. 23. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: * *Medical*. *Written*. Hartford, March 11-12. *Endorsement*. Hartford, March 25. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Homopathic*. Derby, March 11-12. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: July 8-10. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: * Washington, May 12-13. Sec., Commission on Licensure, Dr. George C. Rubland, 203 District Bldg., Washington.

FLORIDA: * Jacksonville, June 23-24. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, June. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Jan. 8-11. Sec., Dr. James A. Morgan, 48 Young Building, Honolulu.

IDaho: Boise, April 1. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, 335 State Capitol Bldg., Boise.

ILLINOIS: *Written*. Chicago, Jan. 21-22. *Reciprocity*. Chicago, Jan. 23. Supt. of Registration, Dept. of Registration and Education, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 17-19. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, Citizens Trust Bldg., Fort Wayne.

MAINE: Portland, March 11-12. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, March 11-13. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: * Ann Arbor and Detroit, June 11-13. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MINNESOTA: * Minneapolis, Jan. 21-23. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: *Reciprocity*. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: *Reciprocity*. Helena, March 31. *Written*. Helena, April 1. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEVADA: *Reciprocity with oral examination*, Feb. 3. Sec., Dr. Fred M. Anderson, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, March 13-14. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, June 17-18. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April 14-15. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 27-30. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, State Education Department, 315 Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, Jan. 7-10. Sec., Dr. G. M. Williamson, 41 1/2 S. Third St., Grand Forks.

OREGON: * Portland, Jan. 14-16. Exec. Sec., Miss Lorianne M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: Philadelphia, January 7-11. Acting Sec., Bureau of Professional Licensing, Miss Marguerite G. Steiner, 358 Education Bldg., Harrisburg.

RHODE ISLAND: * Providence, Jan. 2-3. Sec., Division of Examiners, Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH DAKOTA: * Pierre, Jan. 21-22. Dir., Medical Licensure, Dr. J. F. D. Cook, Pierre.

VERMONT: Burlington, Feb. 11. Sec., Dr. W. Scott Nay, Underhill.

WASHINGTON: * Seattle, Jan. 13-15. Sec., Department of Licenses, Mr. Nelson N. Vaughan, Olympia.

WEST VIRGINIA: Charleston, March 3. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: * Madison, Jan. 14-16. Applications must be on file not later than Jan. 2. Sec., Dr. H. W. Shutter, 425 E. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, Feb. 3-4. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

CONNECTICUT: Feb. 8. Address State Board of Healing Arts, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, April 21-22. Sec., Commission on Licensure, Dr. George C. Rubland, 203 District Bldg., Washington.

FLORIDA: De Land, June 7. Applications must be on file not later than May 24. Sec., Prof. J. F. Conn, John B. Stetson University, De Land.

JOYA: Des Moines, Jan. 14. Dir., Division of Licensure and Registration, Mr. H. W. Grete, Capitol Bldg., Des Moines.

MICHIGAN: Ann Arbor, Detroit and East Lansing, Feb. 14-15. Sec., Miss Flora E. Dube, East Lansing.

MINNESOTA: Minneapolis, Jan. 7-8. Sec., Dr. J. Charnley McKinley, University of Minnesota, 126 Millard Hall, Minneapolis.

NEBRASKA: Omaha, Jan. 14-15. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

OREGON: Portland, Feb. 15. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Feb. 19. Sec., Division of Examiners, Rev. Nicholas H. Serroc, Providence College, Providence.

WASHINGTON: Seattle, Jan. 9-10. Sec., Department of Licenses, Mr. Nelson N. Vaughan, Olympia.

Oregon June Report

Miss Lorianne M. Conlee, executive secretary, Oregon State Board of Medical Examiners, reports the written examination for medical licensure held at Portland, June 18-20, 1940. The examination covered 11 subjects and included 80 questions. An average of 75 per cent was required to pass. Thirty-one candidates were examined, all of whom passed. Four physicians were licensed to practice medicine by reciprocity and 3 physicians so licensed by endorsement. The following schools were represented:

West Virginia July Report

Dr. Arthur E. McClue, secretary, Public Health Council of West Virginia, reports the oral and written examination for medical licensure held at Huntington, July 1-3, 1940. The examination covered 11 subjects and included 110 questions. An average of 80 per cent was required to pass. Twenty-five candidates were examined, all of whom passed. Sixteen physicians were licensed to practice medicine by reciprocity and 1 physician so licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....		(1939)	85.9

Book Notices

Public Health Administration in the United States. By Wilson G. Smillie, A.B., M.D., Dr.P.H., Professor of Public Health and Preventive Medicine, Cornell University Medical College, New York City. Second edition. Cloth. Price, \$3.75. Pp. 553, with 31 illustrations. New York: Macmillan Company, 1940.

Since the first edition of this book appeared five years ago there have been some extraordinary developments in public health administration in the United States. Some of these have been associated with new scientific information, such as that regarding scarlet fever, measles, influenza, the venereal diseases and particularly pneumonia. The relationship of nutrition to the public health has become more clearly defined, and the modern health department is greatly concerned with the general nutritional state of the people. The Social Security Act of 1935 revolutionized our national health program and modified greatly the administration of public health procedures. Dr. Smillie has reflected these changes in the new edition of his book, and he discusses the consolidation of the gains that have been made and the possibilities for the future. There is no longer any necessity for discussion as to the place of the public health officer in modern civic organization. However, the exact position which he is to occupy in relation to other phases of the public health is still a matter of considerable debate. It is well to find Smillie saying "The United States Department of Agriculture has estimated that one third of our population cannot afford to purchase even a minimum adequate diet. In our opinion this is a highly exaggerated statement." Of particular importance is a chapter on the practicing physician and the public health department. This material should be in the mind of every practitioner. A concluding chapter on the national health program discusses the present trend toward new legislation. Dr. Smillie is convinced that the United States is not ready for a nationwide plan of sickness insurance. He points out that we are not a totalitarian nation, that nationwide philosophies must develop slowly and must win the approval of the people who are to be benefited. Neither does he feel that our present organization of public health is ideal. Evolution is going on, and Dr. Smillie suspects that administrative devices which have not yet been initiated will eventually supplant our present type of organization.

Office Clinical Chemistry: A Laboratory Guide for the Practitioner and Hospital. By Emanuel M. Abrahamson, B.S., Ph.D., M.D., Adjunct Attending Physician, the Jewish Hospital of Brooklyn, Brooklyn. Cloth. Price \$5. Pp. 245, with 39 illustrations. New York, Toronto & London: Oxford University Press, 1940.

This volume is designed to aid the clinician by selecting chemical methods for the examination of blood and urine which are suitable for office practice. It is not intended as a supplement or substitute for the existing treatises on laboratory procedures suitable to the large hospital laboratory with extensive equipment.

In general, the author has made an excellent selection of more than sixty established procedures adaptable for office practice. Many procedures have been modified so as to eliminate needless duplication of solutions of slightly different concentrations and apparatus of similar nature. A flow sheet of apparatus, reagents and order of procedure is graphically presented with each method in an attempt to simplify the technic. It is hoped that such an attempt at simplification will not mislead the clinician into the belief that preliminary training is not necessary in order to carry out accurately the various procedures. A knowledge of fundamentals is essential to recognize causes for inaccuracies.

While different workers in clinical laboratories may disagree with the author in certain of his selections and modifications of technics, it is obvious that in the main the selection has been wisely made with much thought toward simplification of procedures as far as is compatible with an accuracy sufficient for clinical interpretations.

To mention what might be regarded as a few deficiencies: The Kingsley method for albumin-globulin ratio is much simpler and more accurate than the one outlined. The newer sulfanilamide reagent N(1-naphthyl) ethylenediamine dihydrochloride gives a more rapid and stable color. Ordinary Exton's reagent for urinary albumin is generally used. Better calcium and phosphorus methods are available. Also, while ten pages is

devoted to the Van Slyke apparatus for determining alkali reserve, followed by a note that the method is hardly suitable for office practice, a more simple and adequate titration method is not given. It would seem simpler also to purchase congo red paper and Nessler's solution. On page 41, in describing the preparation of protein-free blood filtrate, the author refers to the flask holding ten times the volume of blood. This would seem insufficient. To mention only one other impression: It would seem that the schema for determining the type of urinary calculus is unnecessarily involved, since the clinician usually desires to know only the type of calculus; that is, whether it belongs to the phosphatic, oxalic, uric or urate group or whether it is the cystine type, which occasionally is encountered.

This volume should serve a need that has long been felt by physicians in office practice and should be of great value to the clinician who desires to obtain clinical laboratory data in selected cases.

Principles of Animal Biology. By Lancelot Hogben, F.R.S., Regius Professor of Natural History in the University of Aberdeen, Aberdeen. Cloth. Price, \$3.75. Pp. 415, with 151 illustrations by J. F. Horrablin. New York: W. W. Norton & Company, Inc., 1940.

This book, by the author of "Mathematics for the Million," lies somewhere between the semipopular book on science and the high school or college textbook. Its reading would be hard going for the average individual untrained in science and yet it is probably not complete or technical enough to serve as a textbook for a formal course although it would be excellent as collateral reading. There are a few errors: The sketch titled the human forearm shows the upper arm instead and is not good at that; the term ergosterol is twice misspelled; the statement that "an adequate minimum (vitamin A or carotin) seems to help resistance to diseases like colds and influenza" is not really warranted. Likewise the statement "The composition of what is now called vitamin E, present in cereal oils and green leaves, especially lettuce, is not yet known" scarcely does justice to the close approach which has been made to accurate knowledge of the structure of this vitamin. Also it would have been well if the statement that complete absence of this vitamin results in sterility from degeneration of testes in the male and resorption of early embryos in the female had been qualified by indicating that this result has been proved only in experimental rats.

The author has compressed a large amount of valuable information on science and has in the main expressed this information clearly. Nevertheless it does not seem to be a popularization that is likely to receive an extensive circulation nor is it quite suitable as a textbook. Perhaps its usefulness in future editions might be increased by some further thought on which of these purposes the book is designed to serve.

A Textbook of Medicine. By American Authors. Edited by Russell L. Cecil, A.B., M.D., Sc.D., Professor of Clinical Medicine, Cornell University Medical College, New York. Associate Editor for Diseases of the Nervous System: Foster Kennedy, M.D., F.R.S.E., Professor of Clinical Neurology, Cornell University Medical College, New York. Fifth edition. Cloth. Price, \$9.50. Pp. 1,744, with 173 illustrations. Philadelphia & London: W. B. Saunders Company, 1940.

Textbooks of medicine increase in size continuously with the advancement of medical knowledge. Thus the present edition of Cecil's Textbook is 130 pages larger than the preceding edition. It appears with a green cover, whereas the previous edition was in blue. The book has been entirely revised and completely reset. One hundred and thirty-one additional illustrations are provided. Unfortunately, the paper used for a volume of this size makes reproduction of half-tone illustrations somewhat difficult, and the reproductions, particularly of x-ray films and of skin conditions, are not of the best. In the present edition there are new articles on equine encephalomyelitis, moniliasis, toxoplasmosis, disseminated lupus erythematosus, chronic bromide poisoning, riboflavin deficiency, uveoparotid fever, regional ileitis, amaurotic family idiocy and gargoylism. There are also new treatises on some of the topics previously covered as the result of the development of new information or the appearance of new research. Dr. Foster Kennedy, associate editor for diseases of the nervous system, has revised some of the chapters in that field. Recent advances in bacteriology have caused the transfer of Carrion's disease to the section on Rickettsial diseases and gangosa to the section on spirochetal infections. This one volume system on the practice of medicine

has earned for itself a high place in its field. The methods of presentation, the excellent editorship, the quality of the bibliography, the publisher's contribution, the excellent arrangement and the index assure for this work a position of leadership.

The Anatomy of the Female Pelvis. By F. A. Maguire, C.M.G., D.S.O., M.D. Third edition. Cloth. Price, 10s. 6d. Pp. 162, with 35 illustrations. Sydney & London: Angus & Robertson, 1940.

It is only forty years ago that we in this country drew rather steadily on British teachers in matters of obstetrics and anatomy and to some extent in gynecology. In their writings we looked for and we continue to look for clarity, sanity and vocabulary. Here we have a fair condensation of the subject, illustrated for the first time in the three editions. To these illustrations there are so many references that one is inclined to scrutinize them. Simplification that adequately depicts essentials is an achievement. In a few of the drawings, as in those of the lymphatics, this is the case, but where diagrams or near diagrams run to crude coarse lines they have little place, particularly with vulvas, where a measure of delicacy may be expected. Nor may a pelvic floor or a tube range twice the average thickness, nor a sacrum carry six sections throughout. Then again certain clinical points hardly fit American practice. A diagnosis of uterine position by the "impulse" rather than through routine bimanual palpation or seizure of the organ is one instance. Another is the repeated warning to take pains to avoid visualizing the vulva unless there is very positive evidence during the course of the examination that it needs inspection, thus setting us back to the early days of the pride in his skill of that doctor who always inserted the catheter under the darkness of the sheet—with the price in cystitis consequent on this modest achievement. This good summary from Australia needs all of it brought up to its best to compete with more successful textbooks.

Taber's Cyclopedia Medical Dictionary Including a Digest of Medical Subjects: Medicine, Surgery, Nursing, Dietetics, Physical Therapy. By Clarence Wilbur Taber and Associates. Fabrikoid. Price, \$2.50; Thumb-indexed, \$3. Pp. 1,488, with 273 illustrations. Philadelphia: F. A. Davis Company, 1940.

This book represents an ambitious project as evidenced by the statement on the title page that it includes a digest of medical subjects—medicine, surgery, nursing, dietetics and physical therapy. It does actually contain an enormous amount of information of value to the medical man besides its service as a dictionary; for example, a table of the clinically significant blood constituents, their normal and pathologic ranges, and a list of phrases and words in four foreign languages devised particularly for assisting a physician in obtaining a history. The book also lists the etiology, symptomatology, physical signs and treatment of diseases. This has led, however, to what is probably the major criticism: The opening two sentences under "Treatment of Diabetes Mellitus," for example, are not wholly acceptable. They read "X-ray applied to the adrenals and pituitary glands is being tried, rather successfully. This relieves the necessity for frequent hypodermic injections of insulin." Similarly the treatment described for arthritis is not really illuminating. It is a doubtful contribution to the best medical interests to include such brief and in some instances distorted discussions of etiology, prevention and treatment of disease in a work of this kind. Nevertheless the amount of information contained in the book is amazing and it will serve as a ready source book for a good deal of miscellaneous information and as a satisfactory medical dictionary. The editor has obtained the help of an excellent group of associates.

A fonocardiografia. Pelo Dr. Dante Pazzanese, chefe do serviço de cardiologia do hospital municipal de São Paulo. Paper. Pp. 160, with 90 illustrations. São Paulo: Prefeitura do município de São Paulo, 1940.

The number of publications dedicated to the subject of phonocardiography is on a steady increase. They deal with the technic of recording, description of new apparatus or interpretation of tracings. In view of the growing interest of the medical profession in heart sound recording there is a need for a comprehensive monograph on this subject. Thanks to his extensive experience, the author was well qualified to fill this gap and he accomplished his task in an enviable manner. After a succinct discussion of the diagnostic and didactic value of phonocardiography and a brief historical review, he describes the most

popular apparatus for heart sound recording and proceeds to analyze systematically the graphs in various cardiac lesions. Cambridge, Minot and Siemens recording apparatus were used by the author. To facilitate the interpretation of the tracings, simultaneous phlebograms or preferably electrocardiograms were made. There is no trace of loquacity, the style is simple, and reproductions of heart sound records are numerous and excellent. The book will prove invaluable to any physician interested in this newest method of examination of the heart.

Bibliography of Swimming. Compiled by Frances A. Greenwood, Department of Physical Education, University of Alabama, Tuscaloosa. Cloth. Price, \$4.25. Pp. 308. New York: H. W. Wilson Company, 1940.

This bibliography is a comprehensive survey of the literature on swimming, beginning with a book published in 1538 and including about 10,000 titles classified under 600 subjects, which range from those directly connected with swimming itself to material on air conditioning, poetry, pools and bathing places, spas and mineral baths, and water softening. References of special medical interest are found under such headings as Corrective Swimming and Underwater Gymnastics, Cripples, Diseases and Infections, Drowning, Physiologic Aspects, and Resuscitation. Author and subject entries, arranged in the same alphabet, are made for each item listed, with complete bibliographic data under the author and English translations of foreign titles under the subject. As a whole, the material seems well organized with a helpful division into specific subject headings and ample cross references to guide the user.

A Research Conference on the Cause and Prevention of Dental Caries. Chicago, Illinois, July First and Second, 1938. Cloth. Price, \$2. Pp. 178, with 4 illustrations. Chicago: The Good Teeth Council for Children, Inc., [n. d.].

This conference, held in July 1938, brought together representatives of eleven of the groups prominent in recent investigations in the field of dental caries from all over the United States and Canada. The proceedings contain not only the original papers but also a complete record of the discussion, which was both generous and critical. It therefore presents quite accurately the status of caries research as of July 1938 and, except for recent work in connection with fluorine and dental decay, gives a fair picture of the situation now, approximately two years later. It should be read not only by those who are interested or engaged in such research but also by all those who are concerned actively or otherwise in the prevention and about the cause of dental caries. It was truly characterized by one of the participants as "one of the most interesting presentations" ever listened to, but the original papers and discussions must be read and studied to be appreciated and evaluated. Even the closing summary by Dr. E. V. McCollum fails to develop the conclusions of the investigators and the results of the efforts through discussion to reconcile contradictions.

The Chronicle of Crichton Royal (1833-1936) Being the Story of a Famous Mental Hospital During Its First Century, and Illustrating the Evolution of the Hospital Care and Treatment of Mental Invalids in Scotland. By Charles Cromhall Easterbrook, M.A., M.D., F.R.C.P.E. With foreword: Some Early Crichton Memories, by the late Sir James Crichton-Browne, M.D., LL.D., F.R.S. Cloth. Price, 25s. Pp. 663, with 103 illustrations. Dumfries, Scotland: Courler Press, 1940.

The Crichton Royal Institution was founded in 1833 on an original estate of 40 acres (later increased to over 800) near Dumfries, Scotland, to care for mental invalids of all kinds. This book constitutes a review of the work of this institution over the intervening years, its staff, its physical additions and many other items of historical interest.

Psychiatry for Nurses. By Louis J. Karnosh, B.S., Sc.D., M.D., Associate Clinical Professor of Nervous Diseases, School of Medicine, Western Reserve University, Cleveland, and Edith B. Gage, R.N., Supervisor, Neuropsychiatric Division, City Hospital, Cleveland. Cloth. Price, \$2.75. Pp. 327, with 34 illustrations. St. Louis: C. V. Mosby Company, 1940.

This book presents psychiatry "with an eye to the peculiar needs of the nursing school of today." In its twenty-nine brief chapters it offers first a historical review of the subject, then the structure and mechanism of the personality, taking up the classification of mental diseases and the examination and management of patients. More detailed consideration is given in later

chapters to the specific types of mental disease and to an outline of the various therapies now in vogue. The practical approach to the psychiatric patient is ably described and the theoretical aspects of psychiatry are brought into clear view. Brevity may account for certain omissions and may permit certain biased statements to creep in. For example, there is disapproval of psychoanalytic therapy without the credit given for the value of psychoanalysis as a key to psychiatric knowledge. Again, in the discussion on the treatment of epilepsy, large doses of bromides are featured without mention of acne and other complications. In the main, the authors have succeeded in preparing a readable book, brief, lucid and interesting. Questions at the end of each chapter, a glossary and an index add to its usefulness.

An Introduction to Pharmacology and Therapeutics. By J. A. Gunn, M.A., M.D., D.Sc., Professor of Therapeutics and Director of the Nuffield Institute for Medical Research, University of Oxford, Oxford. Sixth edition. Cloth. Price, \$1.75; 6s. Pp. 242. New York & London: Oxford University Press, 1940.

Like its predecessors, the present edition of this well known little book provides the prospective student of pharmacology with a satisfactory didactic survey of the subject. The fact that six editions have appeared in ten years would seem to indicate that British students are well pleased with this method of approaching their course in experimental pharmacology. Doubtless the author requires supplementary reading of the more exhaustive textbooks in his own classes, as indeed he indicated in the preface to the first edition of this work; one would think, however, that there might be some danger of the lackadaisical type of student being satisfied with the preliminary sketch and never going on to a study of the larger canvas.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Libel: Publication Exposing Quackery Privileged Under State Statute.—In an article published in *Hygeia* entitled "Modern Medical Charlatans," the defendant, among other things, accused the plaintiff, John R. Brinkley, of being the apotheosis of quackery and of having made as much as \$55,000 a week "from his various quackeries." The plaintiff later brought suit in the district court of the United States for the western district of Texas to recover actual and punitive damages for libel. The defendant pleaded the truth of the statements of fact in the article and that matters of opinion contained therein were based on facts and were his reasonable and honest opinions and so were privileged within the meaning of the Texas statute which declares that reasonable and fair comment or criticism of matters of public concern published for general information shall not be made the basis of an action for libel. The proceedings of the trial were published in J. A. M. A. 112:1952 [May 13], 2050 [May 20], 2138 [May 27] and 2280 [June 3] 1939. Judgment was rendered for the defendant and the plaintiff appealed to the United States circuit court of appeals, fifth circuit.

Under the statutory law of Texas, said the circuit court of appeals, the truth of statements in publications is a defense to an action for libel even though the words are actionable per se. The testimony of the plaintiff tended to show the truth of the statements of fact complained of and there was no substantial evidence tending to show that the defendant was actuated by malice or that the plaintiff suffered any actual damage compensable in money. There remains to be considered, continued the court, but one more question—whether the expressions of opinion in the defendant's article were privileged under the laws of Texas. The gist of the defendant's article was that the plaintiff is a charlatan and a quack. According to the Century Dictionary, said the court, a "charlatan" is defined as "one who pretends to more knowledge or skill than he possesses, especially in medicine; a quack." A "quack" is defined as "an ignorant or fraudulent pretender to medical skill," and an

element of quackery is "to advertise or urge, as a quack does his remedies." With respect to the plaintiff's professional qualifications and activities, continued the court, the admissions in his testimony tended to show:

that he obtained his medical degree from an institution known as a diploma mill; that he had been practising medicine since 1915; that he began practising medicine in Milford, Kansas, in 1917; that he advertised, by pamphlets and newspapers and by radio broadcasting from his own station, an operation for transplanting goat glands in men for the purpose of sexual rejuvenation; that he had treated between 5,000 and 6,000 persons and he charged some of them nothing and some of them \$750 for the operation; that his gross income was about \$100,000 per month; that he abandoned this practice in 1933; that his license to practice medicine in Kansas was revoked in 1930 and his radio license was revoked by the Federal Communications Commission in 1930; that a license he had obtained to practice medicine in Connecticut was revoked; that he was indicted in California for a conspiracy to unlawfully practice medicine; that at the time the article was written he was advertising, by radio broadcasting from a Mexican station, his skill in treating prostatic troubles; that he would prescribe by letter for persons who wrote to him describing their symptoms, for which he charged \$2.

All learned professions have their standards of ethics. A lawyer who advertises and gives advice by mail without seeing his client would certainly be considered a shyster. There was no doubt whatever that the plaintiff by his methods had violated accepted standards of medical ethics. In the judgment of the court, the facts quoted above were sufficient to support a reasonable and honest opinion that the plaintiff was a charlatan and a quack in the ordinary, well understood meaning of those words. The information contained in the defendant's article, concluded the court, was a matter of public concern and, since the article was published for general information, the published statements complained of were privileged. Accordingly the circuit court of appeals affirmed the judgment for the defendant. A petition by the plaintiff for a writ of certiorari was denied by the Supreme Court of the United States.—*Brinkley v. Fishbein*, 110 F. (2d) 62; 61 Sup. Ct. 34.

Libel: Baker Hospital Not a "Public Institution."—Defendant Norman Baker, the founder and owner of the Baker Hospital at Eureka Springs, Ark., in June 1939 wrote an open letter to Mr. and Mrs. Ray Freeman, residents of Eureka Springs, and to the Eureka Springs Boosters' Association and caused it to be published in a local newspaper, the *Daily Times Echo*. Mr. Freeman was a city official, a member of the Eureka Springs Boosters' Association and of the chamber of commerce and was financially interested in a wholesale grocery store, a swimming pool and a tourist camp. In this letter Baker used language tending to impeach the honesty, integrity, veracity and reputation of the Freemans. He accused them of making unfavorable comments about the Baker Hospital to persons who stopped at their tourist camp, persons who would otherwise have become patients of his hospital and would have spent a large amount of money in the city. He pointed out that all the local merchants would make more money if the Freemans desisted from actions which "are tearing down the good the Baker Hospital is doing." He said that the Freemans advised their patrons at the tourist camp to investigate about town before going to the Baker Hospital because it was a horrible and unfit place and had no licensed doctors. Finally he recommended that the boosters' association and the chamber of commerce expel Mr. Freeman from membership in their respective organizations and further that they sponsor a movement to oust or remove Mr. Freeman from city office. In conclusion he wrote:

Can the citizens expect the Baker Hospital and other progressive citizens to give good co-operation as long as these ungentlemanly, underhanded and contemptible things exist?

On the basis of this letter, which the jury found contained false and untrue statements, the defendant was convicted of criminal libel in that he unlawfully, wilfully, maliciously and falsely exposed the Freemans to public hatred, contempt and ridicule. From this conviction Baker appealed to the Supreme Court of Arkansas.

Baker attempted to justify his remarks on the ground that the open letter was a privileged communication. His theory was that the Baker Hospital was a public establishment depending on the public for support and that therefore he had the right to defend that institution from unjust and malicious attack, as contained in false or untrue statements. The Supreme

Court, however, held that the Baker Hospital was not a "public institution" but was a purely private enterprise, and that it depended on public support only in the same manner and degree as does any other community enterprise, be it a department store, barber shop or meat market. There was nothing in the record to indicate that the Baker Hospital was an organized charity conducted in the public interest. Furthermore, said the court, in the first paragraph of the published letter the defendant assumed full responsibility for the statements contained therein and attempted to absolve the Baker Hospital from any blame that might follow from the publication when he stated: "It is understood that I write this personally, without any connection with the Baker Hospital, but as an honest and progressive citizen, interested in the welfare and upbuilding of the community." In the judgment of the court, this statement conclusively showed that the communication was not a privileged one and was not so regarded by the defendant himself. Accordingly, the Supreme Court of Arkansas affirmed the judgment of conviction of libel. Baker then petitioned for a writ of certiorari to the United States Supreme Court, but his petition was denied.—*Baker v. State (Ark.)*, 137 S. IV. (2d) 938; 61 Sup. Ct. 25.

THE AMERICAN RHEUMATISM ASSOCIATION

Seventh Annual Meeting, held in New York, June 10, 1940

DR. LORING T. SWAIM, Boston, Secretary

(Concluded from page 2116)

An Oft Recurring Disease of Joints (Arthritis, Periarthritis, Para-Arthritis) Apparently Producing No Articular Residues

DR. PHILIP S. HENCH, Rochester, Minn.: The outstanding features of an unusual articular disease are multiple afebrile attacks of acute arthritis and periarthritis, sometimes also para-arthritis, with pain, swelling, redness and disability generally of only one but sometimes of more than one small or large joint of adults of either sex. The attacks appear suddenly, develop rapidly, generally last only a few hours or days and then disappear completely, only to recur at short or long irregularly spaced intervals. Despite the (transitory) presence of an acute or subacute inflammatory reaction in joint tissues and a fibrinopurulent exudate in the articular cavity (in some cases) there is little or no constitutional reaction or abnormality in laboratory tests, and no significant functional, pathologic or roentgenographic residues occur even after years of disease and scores or even hundreds of attacks.

Of the thirty-four patients nineteen were females, fifteen males. At the onset of the disease the patients were from 13 to 68 years of age (70 per cent were from 20 to 39). The disease had lasted from three months to twenty-five years, a total of 242 (average seven) years. Attacks had occurred at the rate

of from two to ten yearly in nine cases, from twenty to sixty a year in seventeen cases, from 100 to 200 a year in three cases, and 250 or more a year in five cases; in the latter cases some joint or other was involved almost daily in a short attack, but successive attacks were not necessarily in the same joint. Four patients had each had "hundreds" of attacks; the remaining thirty patients had had a total of at least 4,930 attacks, an average of at least 164 attacks per patient within the average of seven years of illness, or twenty-three attacks per patient yearly.

The attacks lasted usually from one to three days, rarely more than one week. The intervals between attacks varied from only one or two days in those most frequently affected to one or six months in others. In 90 per cent of cases attacks were usually monarticular; occasionally two or more joints were simultaneously involved. Favorite sites were a finger joint, wrist, shoulder, knee, toe or elbow but practically any joint was liable to attack. Attacks appeared suddenly and progressed rapidly. Pain was sometimes mild, generally a severe ache, occasionally severe enough to require narcotics. Disability was considerable, producing temporary loss of function of the affected joint. Some patients were often forced to go to bed.

Red, tender, painful para-articular swellings occasionally appeared in 30 per cent of the cases at characteristic sites; they lasted only six to twenty-four hours; they differed from angioneurotic edema. In three cases intracutaneous or subcutaneous nodules also occurred occasionally, generally on the fingers.

There was little or no constitutional reaction, no fever in any attacks observed, no loss of appetite, generally no weight loss. Anemia was absent in 94 per cent. Total white counts were generally normal, but a relative lymphocytosis without eosinophilia was generally present. Sedimentation rates were generally normal between attacks and generally but not always slightly elevated during attacks (the average of thirty-three tests was 24 mm.). A moderate lipemia was present. Of the 164 roentgenograms of joints made, 150 (91 per cent) were entirely negative; the rest revealed coincident unrelated disease (bunions, hypertrophic changes in elderly patients).

Biopsies made during attacks (three cases) revealed an acute or subacute inflammation in synovial membrane and capsule, sometimes in tendon sheaths, and a fibrinopurulent exudate in the joint cavity. A biopsy of a knee between attacks revealed no gross or microscopic abnormalities.

The cause of the disease was not determined. The evidence collected against an allergic hypothesis outweighed that for it. Cultures of biopsy material were negative. Differentiation of this condition from atrophic arthritis, intermittent hydrarthrosis and gout was made. The cases possessed many of the features of the "angioneural arthrosis (periarthrosis, parathyrosis)" of Solis-Cohen (1913) or of Kahlmeter's (1939) "allergic articular and periarticular rheumatism," but certain differences were described.

Treatment included epinephrine, ephedrine, benzedrine, ergotamine tartrate, removal of foci, autogenous vaccines, low purine diets, diets free of suspected foods, histaminase, histamine desensitization and typhoid vaccine reactions. None of these methods gave impressive results. Follow-up data on twenty-seven cases were reported. A cure (spontaneous?) had occurred in four cases (15 per cent), slight improvement in twelve cases (44 per cent) and no change in seven cases (27 per cent); three patients (11 per cent) were having more frequent (but not longer) attacks. One patient died of coronary disease. There appeared to be no tendency for the disease to become chronic in a given joint. Despite the thousands of attacks suffered during a grand total of 307 years of illness (242 prior to plus sixty-five years since admission) no permanent crippling had affected any joint.

DISCUSSION

DR. K. K. SHERWOOD, Seattle: No matter how detailed and clearcut the description of a syndrome of arthritis is, it warrants reemphasis that this syndrome portrays a variant from the ordinary forms of chronic infectious arthritis both as to etiology and as to cause and is not a new disease but a variation. With this reservation I feel that the splitting of chronic arthritis not only into the hypertrophic and atrophic group but into smaller

subdivisions of clinical syndromes is of great value prognostically and therapeutically. This description may be held as a classic example of how each individual syndrome of chronic arthritis should be described and isolated if it is to be considered as a variant. Several years ago Dr. Hench described the occasional startling remissions occurring in chronic infectious arthritis with the onset of jaundice. Essentially each of these attacks resembled a case of chronic infectious arthritis of hours' duration rather than of months' duration. I have observed early cases of atrophic arthritis in which the joint symptoms preceded the constitutional manifestations of the disease and feel, therefore, that this syndrome might be regarded as an abortive form of true infectious or atrophic arthritis. It would seem worthy of detailed investigation in the cases described by Dr. Hench to determine whether or not a factor of abnormal liver metabolism might not be the reason for the nonprogression of these cases. A detailed study of the liver function in these cases might be of value in aiding one in learning why jaundice occasionally is of such dramatic therapeutic value.

DR. RUSSELL L. CECIL, New York: I cannot recall having seen a case exactly like the cases described, though I am sure we have all had the experience from time to time of seeing cases of joint swelling which we could not classify. I recall several in which I suspected an angioneurotic phenomenon. I am not referring to classic intermittent hydrops. I have seen several of the latter develop typical rheumatoid arthritis. Dr. Hench's cases should not be confused with intermittent hydrops, and the disease should not be called rheumatoid arthritis because of the lack of constitutional reaction and the failure of the disease to make any permanent changes in the joint. There is no progress toward chronicity and no injury to the synovial membrane. It seems that Solis-Cohen looked on this condition as an angioneurotic phenomenon, while Kahlmeter leaned more toward the allergic point of view. Dr. Hench has shown in his pictures that an actual leukocytic exudate was present in more than one case. It would hardly be fair, therefore, to call such a condition a purely angioneurotic state. I believe that the hypersensitive joint is something we are just beginning to understand.

DR. RALPH K. GHORMLEY, Rochester, Minn.: It has been my privilege to see a few of these patients from time to time with Dr. Hench, and I wish to corroborate as far as I am able the statements he has made and the facts he has presented, particularly as far as the pathologic changes are concerned. I have examined these tissues and they do not present a picture of infectious arthritis. The leukocytic exudation is more striking in some of the specimens than in those he showed on the screen.

DR. WALTER BAUER, Boston: It is too soon to say that the thirty-four patients described by Dr. Hench are suffering from one and the same disease. I myself believe that follow-up studies will show that he has included a number of diseases. On the other hand, it must be realized that from 5,000 to 6,000 cases of joint diseases are seen at the Mayo Clinic each year. Therefore it is conceivable that he has gradually weeded out thirty-four patients suffering from a rare disease or syndrome. His figures are not as impressive as they would appear at first glance, 642 years of the disease without any residual of joint changes. If one scrutinizes his analysis, one finds that five patients had the disease less than one year and another ten less than five years. I believe it is impossible to say what these fifteen patients are suffering from. The pathologic changes described could fit any number of acute diseases involving articular tissue. Oft repeated sedimentation rates, leukocyte counts and rectal temperatures on all these patients would be of considerable diagnostic help. One must further realize that diseases may vary considerably in clinical pattern. The same disease in one patient may be extremely atypical and benign, and in another individual it may have a malignant course. This group may have included atypical examples of rheumatic fever, rheumatoid arthritis, gout and allergic diseases.

DR. J. ALBERT KEY, St. Louis: I think this is definitely a disease syndrome. One cannot expect them all to last fourteen years. I should like to know whether there was any preponderance of eosinophils in the sections. Any acute reaction that lasts

a few days will give a polymorphonuclear leukocytic exudate. I have seen one or two and thought they were allergic. They do resemble an abortive gout.

DR. PHILIP S. HENCH, Rochester, Minn.: There was no notable increase of eosinophils either in the circulating blood or in the sections of inflamed tissue removed for biopsy. When I use the term "new syndrome" I refer to one which is new to the consciousness of the general practitioner and even to the "rheumatism specialists" of today. The disease, of course, is not new, and Solis-Cohen and Kahlmeter may indeed have described the same disease. In describing a new syndrome it is difficult not to adulterate the series with cases which do not belong to it. It is therefore natural to suggest that I have fallen into such an error and included cases which in time will be recognized as somewhat atypical rheumatoid arthritis or rheumatic fever. However, I feel that I have already excluded such cases; I discarded a few cases that at first resembled those of the series in some degree but in which within a few months to two or three years the patients began to have longer and longer attacks, which finally became continuous. But there remains a group of thirty-four patients observed over a total period of 307 years, almost ten years each, who present the characteristic and unusual clinical picture which I have described. Do we have the right to consider them to have atypical atrophic arthritis and then wait for the permanent residual intra-articular changes of atrophic arthritis to show themselves? We must be open minded; we must not give a new name to every variety of one disease, but at the same time we must be ready to recognize a new syndrome when faced with it clearly and repeatedly. However, three of these patients were physicians, one a distinguished orthopedic surgeon. Having studied their own disease long and intensively, to them the diagnosis of atrophic arthritis or any other recognized syndrome had long since become quite untenable. We are now seeing seven to nine cases a year and the condition may be commoner than is now apparent. We shall certainly follow our cases closely and I hope to report again concerning them at a later date.

The End Results of Synovectomy of the Knee Joint

DRS. R. K. GHORMLEY and D. M. CAMERON, Rochester, Minn.: A review of the end results in cases in which synovectomy has been performed at the Mayo Clinic reveals the fact that synovectomy has been performed 103 times on eighty-eight patients. Of these, fourteen underwent bilateral synovectomy and one underwent synovectomy of an ankle in addition to synovectomy of both knees. Without resorting to argument as to the feasibility of synovectomy for other joints, we believe that it is a procedure most adaptable to the knee joint, and that other joints can be left out of consideration in this abstract. The operations were performed for chronic synovitis, chronic infectious arthritis, traumatic arthritis, synovial osteochondromatosis, xanthoma of the synovial membrane, intermittent hydrops, tuberculosis, hypertrophic arthritis and chronic synovitis which later developed into polyarthritic involvement, but which in all probability was chronic infectious arthritis at the onset. Of the patients undergoing this operation, end result studies show that three are dead (one from operative shock), and the end results are known in ninety cases in which operation was performed. Of the ninety patients, 34.4 per cent are in excellent condition, 33.3 per cent are improved, and 32.2 per cent are in poor condition, at the time of writing. Studying the end results by groupings, it is found that all the patients with traumatic arthritis, osteochondromatosis, xanthoma and hypertrophic arthritis were either cured or improved. Of the patients who had chronic synovitis, 77.4 per cent were cured or improved, whereas 56.2 per cent of those who had chronic infectious arthritis were improved or cured and 54.9 per cent of those who had synovitis which later developed into chronic infectious arthritis were improved or cured.

DISCUSSION

DR. PAUL P. SWETT, Bloomfield, Conn.: By a slight rearrangement of the figures it is found that out of fifty-two cases of atrophic arthritis only twenty-four showed a combination of improved or excellent results. Thus the authors' figure of about 50 per cent improvement agrees with Dr. Inge's recently reported conclusion that synovectomy offers a chance of helping about

half of the cases of atrophic arthritis. This means that we are not yet able, after nearly twenty years' experience, to define the conditions under which synovectomy can be expected to yield a high percentage of good results. This is especially unfortunate because it is highly important to be able to give exact indications for any operation which might add to our resources for managing the great group of the chronic arthritides which is most in need of treatment and in which synovectomy sometimes yields brilliant results. To clarify this situation it may be said that the successful use of synovectomy must be based first on consideration of the type of the disease and second on the stage of the process. Under the type of the disease it must be remembered (1) that the operation is applicable only to a synovial proliferative process, (2) that, as was first shown by Nichols and Richardson and later confirmed by Allison and Ghormley, the characteristic pathologic change in atrophic arthritis is proliferation but, while this commonly first occurs in the synovia, it also occurs in the perichondrium, the endosteum and the epiphyseal connective tissue and (3) that, as has been emphasized by Pemberton and Osgood, there are two important variants of the disease in which either capsular fibrosis or muscular fibrosis is the predominant characteristic. Hence in the selection of the candidates for synovectomy it is necessary to exclude those cases in which the proliferative process is not primarily and predominantly synovial as well as those variant types which obviously are not suitable for this form of treatment. The stage of the process in which synovectomy may be most useful is (1) as soon as it can reasonably be determined that the proliferation is not going to undergo spontaneous resolution, (2) before the proliferation has caused irrevocable damage to the joint structures and (3) before protracted invalidism has so depleted the patient that no form of treatment can any longer be helpful. It is probable that the failures of synovectomy are to be found among those cases in which the disease was not primarily and predominantly synovial or in those instances in which the operation was done too late. Further reports on this work should be based on a series of observations in which the conditions outlined have been fulfilled.

DR. FRANK D. DICKSON, Kansas City, Mo.: It has been my experience over the last twenty years in some 140 synovectomies that proper removal of the synovia and other material in an infected joint results in a large percentage of cases in improvement in other joints. It is something that happens far too often in my experience to be ignored. I believe that many failures in synovectomy are traceable to an incomplete operation. If one simply removes the synovia and leaves behind disintegrated semilunar cartilages and joint cartilage which is partly or largely destroyed by pannus, and projecting hypertrophic margins, one cannot expect a good result. Synovectomy to be successful must be complete, and this in the knee always includes removal of the semilunar cartilages, removal of all cartilage destroyed or partly destroyed by pannus, removal of all hypertrophic osteophytes, and reducing the joint surface to an area represented by the cartilage which was considered satisfactory enough to be allowed to remain in place. If more thorough, more complete, operations were done the results would be better. Only a few months ago I did a complete synovectomy on a right knee and a partial one on the left. The patient came back after two months with the right knee in excellent condition but the left knee about as bad as it had been before. I then operated on the left knee again and did what ought to have been done in the first place, a complete synovectomy, with later a satisfactory result on the left knee also. I believe the result obtained by synovectomy is entirely dependent on the thoroughness of the operation performed.

DR. J. ALBERT KEY, St. Louis: I have seen some of Dr. Dickson's cases and I am convinced that he is right. By doing a radical synovectomy in some of these early cases of presumable rheumatoid arthritis in which the principal disease is in one or both knee joints, his results are good. In intermittent hydrarthrosis this is the operation of choice even though it does not always cure.

DR. RALPH K. GHORMLEY, Rochester, Minn.: I agree with Dr. Swett that the selection of the cases is the important thing. We have tried to select cases only when the synovial membrane was involved and the articular surfaces were intact. Dr. Dick-

son's cases were more advanced. It seemed to me that he has opened up a further indication for this operation by doing a more complete operation. It is helpful to put on casts for ten days and then start movement—passive movement at first, then later active movement. Later, manipulation for three or four weeks may be helpful.

Experiences with Roentgen Therapy in Various Rheumatic Conditions

DRS. C. J. SMYTH, R. H. FREYBERG and W. S. PECK, Ann Arbor, Mich.: One hundred patients, the majority of whom had characteristic rheumatoid arthritis, others having rhizomelic spondylitis, degenerative joint disease or so-called fibrositis, were given roentgen therapy to some of the joints. For the most part, patients were selected having pairs of comparably affected joints and in such cases roentgen treatment was applied to only one of the pair, the other untreated joint serving as a control. In still other cases the possible psychic effect of such treatment was studied by screening some joints with lead so that no x-rays reached the skin. The effect of such treatment was measured by careful study of the subjective response, physical changes at the joints, frequent erythrocyte sedimentation rate determinations, diagnostic x-ray examinations of the joints, changes in joint fluid from both treated and untreated joints before and after roentgen therapy and in several cases by microscopic study of joint capsule and synovial biopsies. The results of treatment are analyzed in regard to the type of disease, the duration of illness, activity and extent of the disease.

DISCUSSION

DR. W. PAUL HOLBROOK, Tucson, Ariz.: Last year Dr. Freyberg discussed sulfur therapy and buried it thoroughly. This year it is roentgen therapy. It will take Dr. Freyberg only a few years to dispose of all our therapeutic agents at the rate he is going. This is a carefully controlled experiment with roentgen therapy. A few years ago Dr. Kahlmeter reported on the subject and I have done a little work with it. Dr. Kahlmeter's cases were certainly not controlled as Dr. Freyberg's have been. My experiences, though small, have been identical with those obtained by Dr. Freyberg in rheumatoid arthritis. I have experienced two differences. First I have had better luck in the control of pain about the shoulder from bursitis with roentgen treatment than Dr. Freyberg indicated. Whether it has anything to do with curing the disease or not I do not know, but if the pain can be controlled it is helpful. Second, I have had no such brilliant results with spondylitis as Dr. Freyberg reports.

DR. LORING T. SWAIN, Boston: This paper represents the beginning of the best controlled study of roentgen therapy to date. The estimate of the results in arthritis is difficult because of the nature of the disease and the psychologic effects of any and all forms of treatment. It is a purely local form of treatment and should not be expected to affect the constitutional disease. No changes have been found in the sedimentation rate; the x-rays cause no beneficial change in the bones or joints. I believe the effect is in the soft tissues and that they appeared gradually less swollen and that ultimately the growing villus tissue in the joints decreased. I believe the chief value is in decrease of pain due to hyperemia in the soft tissues. Spasm is consequently less and motion increases. My colleagues and I were not particularly impressed with the psychologic effect of roentgen treatment in our cases and therefore did not use a lead screen. This is a valuable addition to methods of control. We have treated one of two joints in many cases, but this does not give an adequate control of the mental factors. We have not stopped other treatments, but in certain cases merely added roentgen treatments.

Roentgen treatment was begun at the Robert B. Brigham Hospital in 1932 of one child whose left knee had been operated on for synovial overgrowth with poor results. X-rays have given her an excellent right knee, eight years later. Up to March 1940 we have completed treatment of 164 patients. Of these eighty-five were for rheumatoid arthritis, thirty-one for osteo-arthritis, twenty-eight for a combination of osteo-arthritis and rheumatoid arthritis and eighteen for Strümpell-Marie arthritis. Treatment was first given for relief of pain, but it

was soon observed that swelling and limitation of motion decreased gradually under roentgen treatment. We have listed the end results according to subjective improvement and objective improvement. By subjective improvement we mean relief of pain and stiffness. By objective improvement we have listed measurable decrease in swelling and measurable improvement in motion. There were no observable roentgenologic changes except that recalcification of the bone was observed somewhat more frequently in patients receiving roentgen treatment in comparison to those not receiving roentgen treatment; this has been mentioned in medical literature. No complications or untoward reactions were observed. In the patients with rheumatoid arthritis, subjective improvement was observed in over 90 per cent of those in whom the swelling and pain in the joints had been of six months duration or less. There was also objective improvement. Of the patients whose arthritis was from six months to two years in duration subjective improvement was observed in about 85 per cent and objective improvement in 60 per cent. Of the patients whose arthritis was of long duration, over two years, subjective improvement was observed in about 72 per cent and objective improvement in 52 per cent. Of the patients with osteo-arthritis there was no appreciable difference between the early, moderately advanced and late cases. These were improved subjectively in 70 per cent and objectively improved in 45 per cent. Of those patients who had evidence of both rheumatoid arthritis and osteo-arthritis there was subjective improvement in only 63 per cent and objective improvement in 25 per cent. In Strümpell-Marie arthritis relief of pain in the back was observed in only three cases. Pain in the hip or shoulder joint was relieved in 50 per cent of the patients; objective improvement was observed in about 15 per cent.

In rheumatoid arthritis, the earlier the case is treated the more rapid is the response. Children seem to respond more quickly to this form of treatment than adults. Frequent small doses continued for a long period of time give better results than larger doses given at longer intervals or for only a few times. In the Strümpell-Marie arthritis improvement was noticed only when twelve or more treatments had been given at fairly frequent intervals—two weeks or less. Improvement was usually observed only after the lapse of a year. Treatment was of three types: For small joints (knee joint or smaller) the following formula was used: 118 kilovolt peak, 5 milliamperes, 1 mm. of aluminum filter, 90 roentgens per minute, two and one-half min. = 225 roentgens, 14 inches distance. For spines, 130 kilovolt peak, 5 milliamperes, 3½ mm. of aluminum filter, 39 roentgens per minute, 5 minutes = 195 roentgens, 14 inches distance. For osteo-arthritis of the knees and hips, 130 kilovolt peak, 5 milliamperes, 3 mm. of aluminum filter, 39 roentgens per minute, 2¾ minutes = 107¼ roentgens, 14 inches distance. These formulas were gradually developed after several years of trial and seemed to be the best in our experience for the conditions listed. Treatments were given on the average of once every two weeks. The formula we believe is important.

I would ask Dr. Freyberg to reserve judgment about his results both objective and subjective until from three to five years has elapsed. Our belief is that early, adequate roentgen treatment of rheumatoid arthritis is helpful locally. It relieves pain in osteo-arthritis, and has helped hips in Strümpell-Marie spondylitis.

DR. EUGENE T. LEDDY, Rochester, Minn.: Most of the cases of arthritis referred to the radiologist for treatment are in the group for which little can be done, and one in which the results of treatment are in no sense outstanding. The technic of the roentgen treatment of arthritis is by no means standardized and is largely a matter of choice of the radiologist. Most of us have a few fairly definite rules which we modify to fit the individual case. My own view is that, since arthritis is a chronic inflammatory disease, the use of both high voltage and high doses is unnecessary. I therefore feel that the technic described by Dr. Freyberg is too intensive. In general, the earlier the stage of arthritis the better is the result, and I think that the more acute the case, the lower should be the dose of x-rays used in its treatment. There is one type of arthritis which I think is unfavorable for roentgen treatment, and that is the group in which there has been deposition of bone. I know of no radiologic technic which will cause dissolution of these bony deposits. However, roentgen

treatment is worth a trial in this group for its possible pain-relieving effect. In many cases of arthritis, relief of pain follows roentgen treatment without there being any changes demonstrable in the roentgenogram to account for it. The explanation of the effect of roentgen treatment on arthritis is somewhat controversial, but I feel that it is largely destruction of leukocytes in the inflammatory process.

DR. ERNST FREUND, Boston: In rheumatoid arthritis as well as in other chronic diseases it is helpful to have a treatment which gives a symptomatic result. In some cases in which inflammation is present the results are better if one first removes the effusion by puncture or by physical or medical means. One of the first indications of periarticular disease is involvement of the shoulder, followed by the hip and knee. In some the results obtained by x-rays are better than with other means. I have never treated women between the ages of 15 and 45 with x-rays for sciatica or sacro-iliac arthritis because I have seen some treatment given elsewhere which resulted in sterility. Some other diseases, such as superficial irritations of the periosteum, like epicondylitis and styloiditis, and similar conditions such as bursitis, respond well to roentgen treatment. I have had relatively good results with this kind of treatment.

DR. JOSEPH A. FREIBERG, Cincinnati: I myself have seen no harmful effects of roentgen therapy but I do not think it should be given in this condition, especially since Dr. Freyberg mentioned that in several of his cases there was an increase in osteoporosis following therapy. Whether he attributed the osteoporosis to the therapy I was not quite certain. We attempt to increase the blood supply, and if high voltage roentgen therapy or any similar treatment is used we may lessen the blood supply to the joint subsequently. I do feel that roentgen therapy is used rather promiscuously in some instances about joints. I have seen extensive osteoporosis following high voltage therapy. I think it would be questionable to use roentgen therapy in arthritis unless it has some very definite effect which cannot be obtained by other means.

DR. R. H. FREYBERG, Ann Arbor, Mich.: I am not a therapeutic nihilist, but I do think that an appraisal of all forms of therapy should be made under controlled conditions and with no undue enthusiasm. Dr. Holbrook mentioned that the results of treatment of spondylitis in his group of patients had not been as brilliant as ours. I do not think our results should be considered brilliant. I contrasted them with results in patients with rheumatoid arthritis, among whom I think they were distinctly poor. We have been encouraged to continue to use roentgen therapy in spondylitis. Diagnosis in the earlier stage of rhizomelic spondylitis is difficult. It is obvious that late in the course of the disease one cannot expect cures from any therapy. If one is going to help these patients one must use treatment of value in the early stage. The patients in whom we observed the best results were those seen early in the stage of development of signs and symptoms characteristic of rhizomelic spondylitis; there was no demonstrable calcification of the paraspinal ligaments; the erythrocyte sedimentation rate was elevated. We have followed our patients, with few exceptions, for at least six months; 50 per cent were observed for more than twelve months, and many for more than eighteen months after treatment. We think this is long enough to get an idea of what effect x-rays will have. We have had no experience in treating younger individuals as Dr. Swaim has. Our patients have always been adults. The technic of irradiation may explain the results that Dr. Swaim mentioned in contrast to ours, though we think it quite unlikely. The development of technic in treatment of rheumatic diseases so far as I can find is about as mysterious as the use of it at all. Dr. Swaim's technic differs from ours in that treatment was given more often and for a longer period. Dr. Freund mentioned getting better results when synovial fluid was removed from the joints later treated. We have observed no difference in aspirated and un aspirated joints. I am glad Dr. Freiberg raised the question about the ill effects. We have had no ill effects except nausea and vomiting lasting for only a few days during treatment. Depilation and pigmentation of the skin occurred in some cases. We saw one patient treated elsewhere who had cutaneous changes indicative of a roentgen dermatitis. I want to add my warning that one should keep in mind the possible harmful effects.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Cardiac Resuscitation from Ventricular Fibrillation.—

Wiggers points out that the high incidence of death from ventricular fibrillation secondary to coronary occlusion and accidental electrocution from electrical appliances make ventricular fibrillation of special interest. The author's experience has convinced him that the physiologic basis for resuscitation rests on the conception that ventricular fibrillation is not a constant phenomenon but an evolving series of changes from the moment of its inception until its cessation, which consumes from thirty to forty-five minutes. Asynchronicity and incoordination involve progressively smaller blocks of myocardium, in which the character of the contraction alters as anoxia progresses because of the cessation of coronary flow. Consequently, restorative procedures must recognize the state which exists at the time the procedures are applied. For example, the atonic stage of fibrillation, in which anoxia causes depression of contractile force and slows conduction, develops in from two to five minutes after the onset of fibrillation. Although fibrillation can be readily stopped at this time, the coordinated beats which redevelop are exceedingly weak and dynamically useless. Consequently, one of the problems of revival consists in finding a means which can be employed within the first three minutes or in devising expedients for more forceful beats. The use of powerful stimulants, such as epinephrine and related substances, must necessarily prove valueless because they cannot substitute for oxygen lack. The author, as well as Wegria, has had success in his experimental work with a modification of the countershock method, which he calls serial defibrillation. The modification consists in applying to the ventricles, through padded electrodes, a series of brief and weaker alternating current shocks. Each shock lasts less than one second and has a strength of approximately 1 ampere; one or two seconds elapse between the shocks. As a rule, from three to seven shocks suffice. The effects are that each successive alternating current shock tends to merge smaller fibrillating areas into larger ones, until a convulsive state is redeveloped. A final shock stops the fibrillation and initiates coordinated beating by natural pacemakers. It is their impression that the deeper myocardium and septum are thus included in fibrillating circuits and, in consequence, these larger circuits are interrupted without the actual passage of currents through the deeper layers and septum. The likelihood of inducing auricular fibrillation is reduced. Since September 1939, out of 328 attempts the author and Wegria have had 327 revivals and they have succeeded forty-one times in one dog. The author suggests that studies be made on larger animals to ascertain whether weaker cur-

rents might not suffice if the method of serial defibrillation were used. The difficulties of meeting the conditions necessary for reviving human fibrillating hearts are analyzed and the conclusion is reached that, although such an achievement is not impossible, remarkable results in the present state of knowledge cannot be anticipated until further methodical research suggests a way of rendering the ventricles less sensitive or refractory to fibrillating agents.

Rheumatic Heart Disease.—Clawson states that if tuberculous pericarditis is excluded, heart failure caused by an adherent pericardium appears in most cases to be the result of rheumatic infection. The condition is seldom seen except in association with rheumatic valvular involvement. From 1910 to 1937, 27,957 necropsies were performed at the University of Minnesota, and 4,254 of these revealed noncongenital cardiac disease (15.2 per cent). In 1,598 (37.6 per cent) of these the disease was infectious in origin (rheumatic, bacterial, syphilitic, toxic myocarditis). There were 796 cases of rheumatic heart disease, comprising about 50 per cent of all cases of infectious heart disease and 18.7 per cent of the cases of noncongenital heart disease. He distinguishes four types of rheumatic heart disease: acute rheumatic endocarditis, recurrent rheumatic endocarditis, valvular deformities and adherent pericardium. The respective incidence of these four types was 12.3, 9.5, 73.5 and 4.52 per cent. Death from acute and recurrent rheumatic endocarditis occurred in the early decades, from incompletely or completely healed valvular deformities in the middle decades, and from the calcific, nodular, aortic valve deformity in the later decades. Death solely as a result of adherent pericardium is rare. The sex incidence was males 27 per thousand and females 31 per thousand. Female patients died earlier than the male patients, probably because in them the mitral valve is most commonly involved. The nature of the inflammatory reaction within the valve was similar to that of frank streptococcal subacute bacterial endocarditis. The valves of the left side of the heart were involved in 99.8 per cent of the patients. There was right-sided involvement in 5.6 per cent, but this was accompanied by a lesion of one or both valves of the left side. The aortic and mitral valves were involved with equal frequency in male subjects. The predilection for the mitral valve in female patients is not understood, but it helps to explain why calcified nodular aortic deformity is common in old men. Vegetations begin on the side of the valve where the spongiosa layer is located, suggesting that the infection may be embolic in origin. However, in some cases small vessels can be seen leading from surface indentations, indicating that infection may occur directly from the blood stream. Auricular endocardial involvement was almost as common in acute rheumatic endocarditis as in bacterial endocarditis. Hypertrophy was present in most of the cases. It was most marked with aortic involvement and less pronounced when only mitral lesions were present. Hypertrophy was more marked among male patients apparently because aortic lesions are more common among them. Proliferative inflammation of a nodular (Aschoff nodules) or diffuse type was common. The stigmas of rheumatic inflammation were practically as common in the valve and myocardium among calcified nodular aortic valve deformities as in mitral valve deformities. All nonsyphilitic aortic valvular deformities which lead to cardiac failure seem to be of rheumatic origin. Tricuspid and pulmonic lesions, especially healed deformities, rarely occur without associated aortic or mitral lesions.

Roentgen Therapy for Inflammatory Conditions.—

According to Desjardins, when acute inflammatory processes, such as furuncles, carbuncles, abscess, erysipelas, parotitis, sinusitis, otitis media, pneumonia (especially delayed resolution in lobar pneumonia), are exposed early enough to a small dose of roentgen rays, rapid diminution of pain and resolution of the inflammation without suppuration follows in a large proportion. If the affected area is exposed after suppuration has developed, pain is relieved more slowly and suppuration is accelerated. When the inflammatory lesion is treated after suppuration has advanced, little or no change in the course of the process is perceived. The rate at which these alterations occur after irradiation corresponds closely to the rate at which lymphocytes, polymorphonuclear leukocytes and eosinophils are known to be affected after irradiation of normal animals. This agrees with the rate at which similar cells of human beings are influenced by irradiation. The influence, varying within certain limits with the dose of rays, consists in the destruction of a proportion of the leukocytes. Since the main effects of irradiation are exerted on cells, the sensitiveness of cells to irradiation is known to be specific for each type of cell and since the leukocytes are the only cells whose radiation sensitivity corresponds to that of acute inflammation it is concluded that the major effect of irradiating such lesions is the destruction of a proportion of the leukocytes infiltrating the inflamed tissues, of those circulating in the blood stream through and around these tissues and of the liberation of the contents of the destroyed leukocytes (antibodies, ferments and so on) into these tissues and into the blood stream. As for chronic inflammations amenable to irradiation, such as many cutaneous diseases, tuberculous adenitis, peritonitis, synovitis, keratitis and iritis, actinomycosis and many others, the pathologic circumstances differ in that leukocytic infiltration is less prominent, but the pronounced feature is proliferation of connective tissue. Connective tissue cells have such a low grade of sensitivity to radiation that they must be classed among the resistant cells. Therefore in chronic inflammatory lesions there is one factor, proliferation of connective tissue, which tends to diminish or retard the action of the rays. This is exactly what is observed in practice. The earlier chronic inflammations are treated, the better they respond. Too often, during the early stage of acute inflammations amenable to roentgen irradiation, the treatment is withheld until the inflammation has progressed beyond hope or until the best results of irradiation can no longer be expected. This situation will no doubt be corrected when more internists and surgeons become acquainted with and convinced of the value of roentgen therapy. A suitable dose of roentgen rays given in time may save some lives and in acute inflammatory processes a small or moderate dose given early will often make other treatment unnecessary.

Arteriovenous Fistulas.—Holman states that since 1923, when Lewis and Drury presented observations on arteriovenous fistulas, 20 instances of this condition have been studied in man before and after their elimination, and numerous experimental animals have been observed before and after comparable fistulas were established between the larger vessels and permitted to remain for as long as seven years. Observations diametrically opposite to those of Lewis and Drury were made in some of the cases. Holman emphasizes the following points: 1. Complete cardiac decompensation with peripheral edema, ascites, hydrothorax and extreme cardiac dilatation may be corrected with a return of the heart to its normal size by eliminating a peripheral fistula. This dilatation involves not only the heart but the great vessels at its base. 2. Early evidence of the malignant influence of a fistula on the circulation—even before dilatation of the heart is detectable—is the behavior of the blood pressure and pulse following closure of the fistula by digital pressure. An increase in blood pressure and a fall in pulse rate indicate that the fistula is large and is one which is not likely to close spontaneously but is almost certain to produce increasing deleterious effects on the circulation. In 1 case, failure to heed this evidence in 1933 when the heart was normal and again in 1936 when the heart was beginning to dilate led to cardiac failure with marked dilatation in 1939. 3. This increase in blood pressure and fall in pulse rate constitute the first evidence that the circulatory bed is beginning to dilate, even though such dilatation may not yet be detectable by the usual means. 4. The extent of this increase and fall depends on the duration of the fistula and is commensurate with the extent of the dilatation of the heart and vessels proximal to the fistula being least in fistulas of short duration and greatest in those of long duration. 5. A temporary but great increase in blood pressure and fall in pulse rate may occur immediately following the operative elimination of a fistula, provided the operation is performed as a physiologic experiment without loss of blood. Despite operations for from four to six hours in 5 cases the blood pressure at the end of the operation was higher and the pulse slower than at the beginning, because of an autotransfusion from circulating blood which had increased in volume during the presence of the fistula. 6. This temporary increase and fall on closing a fistula are dependent on an increase in total blood volume, which is an inevitable accompaniment of a fistula of large size and long duration. 7. The increased blood volume is reduced immediately following operative removal of a fistula by a reduction in the plasma and a concentration of the erythrocytes and hemoglobin. 8. The increased blood volume may result in a transient overdistention of an already dilated heart following operative closure of a fistula, owing to a redistribution of the circulating blood, the volume of blood formerly diverted through the fistula into the capacious venous system now filling the central arterial bed. 9. Eight peripheral fistulas were eliminated by excision or ligation of segments of the main vessel to a limb

without any evident effect on the viability of the tissues beyond the ligature. In 1 case the common, deep and superficial femoral arteries were all ligated without nutritional impairment or function of the leg. This is explainable on the basis of the stimulus to collateral circulation that is provided by the area of diminished peripheral resistance at the site of the fistula, which attracts blood to it through all available channels. 10. When quadruple ligation of the vessels proximal and distal to the fistula is indicated, it would be desirable to ligate and divide the artery proximal to the fistula rather than to ligate it in continuity. In 1 case the fistula was reactivated by the ligature cutting through the arterial wall and reestablishing the lumen of the artery.

Surgery for Aneurysm of Abdominal Aorta.—According to Bigger, from 1817, when Sir Astley Cooper first ligated the abdominal aorta, to 1920 none of the 18 patients in whom the aorta was occluded for abdominal aneurysm survived to leave the hospital. Since 1920, 7 of 12 similar patients have been discharged from the hospital as improved and 1 other lived four and one half months but did not leave the hospital. While it is not certain that any of these patients have been cured, the results demonstrate that occlusion of the aorta is not necessarily fatal. The 2 of the 12 cases in which operation was performed by the author are reported. The first patient was a poor surgical risk in whom left-sided heart failure with pulmonary edema developed. He died following occlusion of the aorta proximal to the aneurysm. The other patient was a young man with a ruptured traumatic (gunshot) aneurysm. He had a preliminary occlusion of the aorta proximal to the aneurysm and one month later a restorative endo-aneurysmorrhaphy. One year later he appeared to be well, there was no evidence of aneurysm and the lumen of the aorta was obviously patent. The author realizes that traumatic and spontaneous aneurysms are widely different and that the treatment used for one may not be applicable for the other. For example, it is unlikely that a spontaneous aortic aneurysm would be suitable for reconstructive endo-aneurysmorrhaphy, but it seems likely that a few spontaneous aneurysms would be suitable for obliterative endo-aneurysmorrhaphy. Such procedures probably should not be attempted unless the aneurysm arises distal to the renal arteries and, almost certainly, not when the aorta is diffusely calcified. Proximal occlusion of the aorta should be a preliminary operation. This brings about shrinkage of the sac so that at the second operation the aorta or the common iliac arteries may be ligated immediately distal to the aneurysm. If the iliac arteries are permanently occluded the ligatures are to be placed on the common iliacs, and the internal iliacs (hypogastrics) should be carefully protected because of their importance as collateral channels. All possible vessels communicating with the sac should be ligated before the sac is opened. Aneurysms of the proximal portion of the abdominal aorta with such essential arteries as the celiac, superior mesenteric or both renals arising from the sac probably should not be treated surgically, while proximal ligation may be justified in aneurysms arising above the renal arteries but without any of the essential arteries originating from the sac. The author states that some of the problems of the surgical treatment of aneurysms of the abdominal aorta may be solved by carefully controlled animal experiments and others only by observations on patients with aortic aneurysms, especially those subjected to operation, and therefore careful reports of such cases are necessary. In his apparently recovered patient fascia was used to occlude the aorta at the first operation. The heavy silk ligature was left around the aorta to occlude it during the aneurysmorrhaphy in case the fascia no longer produced subtotal occlusion. The iliac arteries were exposed and heavy ligatures (tapes would have been better) passed around them for the control of retrograde bleeding when the sac was opened. In spite of these precautions there was considerable pressure in the aorta, presumably from the lumbar and middle sacral arteries which entered the aorta below the occlusion. The author is of the opinion that the strip of fascia has now completely disappeared and that the lumen of the aorta is fully restored.

Hypertonic Dextrose for Pruritus and Serum Sickness.—Stout and Kositchek observed the therapeutic effect of hypertonic solution of dextrose on patients with serum sickness and certain types of pruritus. A 5 per cent solution of dextrose by hypodermoclysis relieved the itching of a patient with exfoliative dermatitis of unknown cause. Thereafter the effects of the solution on patients with other pruritic diseases were determined. The results have been sufficiently consistent and have been sufficiently controlled to represent reliable material. In some of the cases the response of objective signs (urticaria) have paralleled the response of the subjective manifestations. The authors have not been able to establish the theoretical basis for the results. At first a 5 per cent solution of dextrose was used subcutaneously; later it was found that the intravenous route was more efficacious. The usual procedure was to administer 50 cc. of a 50 per cent solution of dextrose and to repeat this, when indicated, or to administer larger quantities of 5 or 10 per cent solutions. In several instances the effects were so instantaneous as to suggest a psychic factor. This factor was ruled out in that isotonic saline solution had no effect in 15 control cases. Of 58 patients who presented pruritus as a prominent symptom 43 were satisfactorily relieved and 15 experienced no relief. Of the 43 who responded satisfactorily, 10 had serum sickness, 7 pityriasis rosea with severe pruritus, 4 pruritus ani, 3 pruritus vulvae, 3 generalized urticaria, 3 dermatitis medicamentosa, 3 generalized exfoliative dermatitis, 2 generalized seborrheic dermatitis and 1 each generalized lichen planus, pruritic papular secondary syphilis, keratoderma climactericum, neoplastic obstructive jaundice, lymphoblastoma cutis, vegetative pemphigus, dermatitis herpetiformis and generalized erythema multiforme. Of the 15 who failed to respond, 5 had infectious eczematoid dermatitis, 4 poison oak dermatitis, 5 senile pruritus, 1 pruritus vulvae, 1 generalized seborrheic dermatitis and 1 atopic eczema with asthma. In the controls after 50 cc. of isotonic saline solution was given intravenously neither objective nor subjective relief was obtained. From one half to several hours after the saline solution was given dextrose was administered with immediate results. In 4 cases in which itching had been a prolonged symptom and in which periodic injections of dextrose controlled the pruritus, substitution of saline solution without the patient's knowledge demonstrated that the dex-

trose produced relief and the saline solution did not. The most noteworthy results were obtained by the 10 patients with serum sickness. The results were immediate, consistent and complete; not only was the pruritus relieved but the accompanying pains in the joints, urticaria and fever. Three of them had previously failed to respond to intensive treatment with epinephrine and calcium gluconate.

Herpes Progenitalis as a Venereal Contagion.—Sharlit believes that the evidence he presents unequivocally establishes herpes progenitalis as a venereal contagion. He presents the histories of 2 patients whose reliability of the pertinent facts argues acceptance of the venereal source of herpes progenitalis and suggests that this clinical entity be included in the group of venereal diseases. The histories are as follows: In February 1928 a white man immediately after sexual intercourse noticed a papule on his penis. That night lightning pains developed in the right groin, and the next morning, when he called on the author, he observed a slight swelling in the right inguinal region. Examination showed a solitary papule on the dorsal surface of the shaft of the penis which was capped by a ruptured vesicle. The skin about the base of the papule was deeply red; a burning pain was present in the lesion and pains radiated to the right groin. The right inguinal nodes were enlarged and tender. The patient had never had a genital "sore" of any kind before. In the preceding twelve months the patient, with one exception, had had sexual relations with only one woman. The exception occurred just six days before his appearance at the author's office. A dark field examination of the lesion showed no spirochetes. A Wassermann test of the woman "of a week ago" was negative. She refused to be examined. A provisional diagnosis of genital herpes was made. Five days after the patient's first visit he returned and brought with him the woman of his constant attention. The night before she had a burning pain in the right vulvar region and on examination an eruption was revealed; tiny vesicles on a deeply congested background on the right labium majus. The condition was typical herpes simplex, the first and only herpes progenitalis that the author has seen in a woman. This woman had never had a genital lesion. The woman's history extended for but one year from her first visit, during which time she had one recurrence of genital herpes in approximately the same region. The man's history has now been available for twelve years. During this time he has had at least a dozen recurrences of herpes progenitalis, on the shaft and on the corona. He has never again had a solitary papule covered by a vesicle but always grouped vesicles. The last two attacks, however, have been on the right buttock. The author believes that his cases are evidences of contagious inoculation, albeit apparently the first. He sees in them missing links in the chain of a rationalized epidemiology. He hopes that careful and detailed studies of the histories of cases of herpes progenitalis will be made to the end that the epidemiology of their infectiousness may be convincingly clarified. The pertinent facts of 2 cases from the private records of Charles Rein of New York are given: A woman, receiving treatment for frequently recurring genital herpes, married during the period of treatment. Nine months after marriage an initial attack of penile herpes occurred in the husband and was followed by recurrences. The rarity of genital herpes minimizes coincidence as explanatory of these 2 cases in conubium. The fact that the husband had approximately nine months of exposure before becoming infected has immunologic significance.

Congenital Atresia of Esophagus.—Lanman presents an analysis of 32 cases of congenital atresia of the esophagus observed at the Children's Hospital during the last eleven years. Thirty of the patients were submitted to operation. A complete necropsy was performed on 2. The observations on the 30 operative cases were supplemented by complete post-mortem examination of 22. Despite the fatal outcome in all of the 30 operative cases, the author believes that considerable progress along rational lines is being made and that successful operative treatment is only a question of time. For a successful outcome it is essential that the condition be recognized during the first few hours of life. Any infant presenting characteristic signs or symptoms of esophageal atresia should have a catheter passed down the esophagus and roentgenograms performed without opaque medium. Immediate operation is imperative if obstruction is present. The author states that anterior gastrostomy is futile unless the lower segment does not communicate with the trachea. Regardless of what procedure other than a direct anastomosis is used for the lower segment, the upper segment must be treated so that aspiration of the overflow of secretions from this blind pouch is prevented. Constant suction is dangerous. Early exteriorization of this upper segment has been advocated and used at the Children's Hospital without success, though, the author states, it is possible that it would have been successful in three of the cases had a posterior esophagostomy not been added to the closure of the fistula at the first operation. Exteriorization of the upper segment commits the patient, if he survives, to a permanent exterior esophagus. Treatment of the lower segment, except in cases with a blind end to the upper and lower segments of the esophagus and in those in which the upper segment communicates with the trachea and the lower segment is blind, must include measures which will prevent contents from the lower segment from entering the trachea. Some of the procedures suggested do not do this. It is the author's belief that no method of attack that does not have as its first step direct closure of the fistula between the lower segment and the trachea has any reasonable chance of success, particularly as regards a primary anastomosis. Direct exposure of the fistula by the extrapleural approach, he believes, should be undertaken. The extrapleural approach seems to be safer than the transpleural. If direct anastomosis is possible it should be done, and if successful and no complication develops the problem is solved, barring possible esophageal stenosis later. If direct anastomosis appears impossible or inadvisable the tracheo-esophageal fistula should be closed and nothing further done at this time. Subsequent procedures as soon as conditions permit are exteriorization of the upper esophageal segment and

anterior gastrostomy. If the patient survives, construction of an exterior connection between the upper esophagostomy and the anterior gastrostomy can then be postponed until a suitable age. An exterior esophagus as a palliative procedure for an elderly patient with cancer is justifiable and endurable, but one dreads to commit an infant to such an existence.

Bleeding Esophageal Varices.—Walters and his associates conclude that esophageal varices develop as a result of obstruction of the portal and splenic veins and that bleeding occurs because of their superficial position in relation to the esophageal mucosa. Banti's disease and splenic anemia are frequently associated with esophageal varices. They cannot be regarded as distinct clinical entities, as they may result from obstruction of the portal or splenic vein. The surgical treatment of splenic anemia has been directed toward removal of the enlarged spleen. Although it has been followed by good results in a large series of cases, the operation does not prevent recurrence of bleeding from the esophageal varices in more than 38 per cent of the cases even when combined with ligation of the coronary vein or with omentopexy. According to Mayo, in about 10 per cent of the cases in which recovery has taken place after splenectomy, death has occurred some time in the next ten years of hemorrhage from the stomach, probably from ruptured varices in the lower end of the esophagus. Although ligation of the coronary vein in the gastrohepatic omentum will serve to interrupt considerable flow of blood through it, the procedure has been used alone in too few cases of splenic anemia to justify any conclusion of its merits in reducing the incidence of hemorrhages from esophageal varices. The recent successful obliteration of esophageal varices by injecting sclerosing solutions into them through the esophagoscope, and their use of the method in 6 cases, lead the authors to believe that the procedure is worthy of trial. Sufficient time has not elapsed to determine whether further bleeding will occur making repetition of the method necessary. The authors believe that the procedure offers a method of controlling bleeding that has not responded to any other form of therapy and thus may be successful in prolonging the life of the patient.

Four Types of Therapy for Pneumonia.—Steincrohn discusses four types of treatment used for 165 pneumonia patients treated in his medical service at the Municipal Hospital during February, March and April of the years 1934 to 1939. The treatments were routine, concentrated dextrose intravenously, serum and sulfapyridine. The mortality for 1934 through 1938 was 35 per cent for all ages. Among patients less than 60 years of age the rate was 20.4 per cent, rising to 60.3 per cent in those more than 60. The mortality in patients with coex-

isting disease was 42.1 per cent as against 17.6 per cent free from complications. Although the mortality rate for the dextrose treated patients was higher (38.4 per cent) than those routinely treated (32.4 per cent) intravenous dextrose therapy has its place in the treatment of individual indications. The average age of the 46 patients who died during the 1934 to 1938 period was 49.3 years and of the 29 given sulfapyridine in 1939 it was 52.3 years. In view of the fact that almost 50 per cent of the patients in the latter group were more than 60 years of age, the sulfapyridine mortality of 8.3 per cent (excluding death within twenty-four hours of admission) is startling as compared with the revised mortality of 30.2 per cent for the patients receiving routine dextrose and serum treatment. In his small series the author observed a definite leukocytic response to sulfapyridine. In the majority of patients who recovered there was a relative leukopenia in from twenty-four to forty-eight hours. The author felt that the absence of a leukopenic response made for a poor prognosis. A marked leukopenia with a normal differential count is no contraindication to the further administration of sulfapyridine. A high concentration of sulfapyridine in the blood does not necessarily indicate a good prognosis. The average number of days of illness before admission in the entire series was practically the same. Patients treated with sulfapyridine were free from fever in an average of 1.6 days, and the 1934 to 1938 group in 9.4 days. The mortality rate of 17.6 per cent among the serum treated patients bears out the accepted experience that serum treatment cuts routine treatment mortality in half. The comparative results of the four treatments demonstrates that no patient with pneumonia should be deprived of the unquestionable aid of sulfapyridine or serum therapy.

Oral Administration of Diethylstilbestrol Dipropionate.

—Weinstein and his associates gave diethylstilbestrol dipropionate orally to 51 women complaining of physiologic menopausal symptoms, to 35 having menopausal symptoms that were initiated by roentgen or surgical treatment, to 6 young women suffering from hypo-estrogen symptoms and to 8 women with atrophic genital changes. The therapeutic regimen for the first group consisted of 1 mg. of diethylstilbestrol dipropionate three times a day. After one week the patient's response to the medication was ascertained and further dosage varied with the individual's reaction. When symptoms were mild or markedly improved the daily dose was reduced to 0.3 mg., whereas the daily dose of those giving little or no response was increased to as much as 15 mg. Twenty-five of these patients were relieved of all symptoms, 16 were improved, 3 showed only slight improvement and 7 exhibited no response. The basis of the treatment of patients with artificial menopausal symptoms was that employed for the preceding group. Individualization of therapy was followed. Generally a large maintenance dose was necessary for relief of this group; 19 were completely relieved, 13 were improved, 2 were slightly improved and 1 experienced no improvement. For the 6 young women exhibit-

ing evidence of hypo-estrogenism (as manifested by menstrual irregularities, headaches, nervousness, irritability, occasional hot flushes, anxiety, depression and diminished libido) individualization of therapy was essential. As most of the complaints were of a cyclic nature, usually preceding or associated with the menstrual flow, the drug was used at that time. All 6 were improved. The atrophic changes of the genitalia in 3 of the 8 women followed artificial menopause, 4 were associated with the physiologic menopausal syndrome and 1 exhibited senile vaginitis without concomitant menopausal symptoms. Here again therapy was individualized. Keratinization of the vaginal epithelium followed the oral administration of the drug. This was observed within as short an interval as one week, and with as little as 7 mg. of the drug. Usually three weeks elapsed and 21 mg. of the drug was necessary before complete relief was obtained. All patients were completely relieved, but recurrences were frequent in from six to twelve weeks after treatment was stopped. Diethylstilbestrol dipropionate orally controls the senile vaginitis, and keratinization of the vaginal epithelium takes place, but the associated atrophic changes do not show the same degree of regression that follows the vaginal administration of biologic estrogens. The only toxic manifestations evidenced by 15 per cent of the women were nausea and vomiting. Only 1 patient was completely intolerant to the drug.

Amphetamine Sulfate for Obesity.—Ersner states that in more than 500 cases of obesity amphetamine sulfate has proved to be the "drug of choice" in obtaining excellent results. No serious complications were encountered. Only obese patients who gave a history of overeating were selected for treatment. After a physical examination the patient was put on a diet of from 1,200 and 1,500 calories daily. This diet consisted of dry cereals, skimmed milk, tea or coffee (without sugar or cream) fresh and stewed fruits, raw and cooked vegetables, one slice of bread with each meal and the choice of from 6 to 8 ounces of meat, fish, chicken, cottage cheese or two eggs daily. The patient was cautioned to limit the intake of fluid and to make certain of a daily evacuation. The patient was given the first week's medication (the smallest possible dose) and thereafter returned every week for a check-up and further medication. The drug was withdrawn at the end of every month or the loss of the first 20 pounds (9 Kg.) and subsequent 15 pounds (6.7 Kg.), and for the ensuing week some brand of vitamin B, C and G was prescribed to make up for any deficiency in the diet caused by the patient's carelessness. After each of these vitamin periods the previous week's dosage was again prescribed and then increased the following week. This permitted the final strength of the drug, one 10 mg. tablet after each meal, to be reached in about three months. The amount of weight to be lost at any one course of treatment was never to be more than one fifth or one sixth of the patient's greatest weight. If the new final weight was far from the nearest calculated normal chart weight (according to height and age), the patient was instructed to return in from four to six months, when again this procedure would be repeated. Thus no patient in the series showed any untoward effects from the loss of weight, even though as much as 60 pounds (27 Kg.) was lost by 1 patient in the course of three months. The average weight lost for the first week amounted to 5 pounds (2.3 Kg.). The average loss for a course of treatment (from three to twelve weeks) was 3½ pounds (1.4 Kg.) per week. With the exception of the vitamin week there were but few occasions when a continuous and sustained loss of weight was not obtained; 100 per cent cooperation was requested. Invariably most of the patients would voluntarily say that they were feeling much better or had much more pep. All agreed that the loss of appetite made dieting easy. With the small graduated doses of amphetamine sulfate employed, the systolic and the diastolic readings, when hypertension was present, usually dropped to normal. Whether this drop toward normal was directly due to the action of the drug or to the loss of weight is a question. Several instances of hypotension became normal during the course of treatment. Normal blood pressures were not affected or were slightly, if at all, lowered. There was but little change in the metabolic rate during the course of treatment. A marked progressive improvement in urines containing albumin, sugar and hyaline and granular casts was observed,

indicating that amphetamine sulfate produces no injurious renal effects. There was little evidence of true addiction. In most instances the medication caused a mild constipation, which was easily remedied with a mild laxative or a simple lubricant, as liquid petrolatum. The reported untoward reactions of the drug should be of much significance to the dispenser and the novice who is about to prescribe it. The patient must be educated as to the possibility of its allergic reactions and of its cumulative effects. Self medication and overdosing must be eliminated to prevent any future fatalities.

Ancient Pronunciation of Medical Words. M. Thebaut, Oakland, Calif.—p. 623.

Kidney Disease and Hypertension.—Ritter studied the relationship between urologic abnormalities and arterial hypertension. He analyzed data from 28 patients with such abnormalities and from 24 patients suffering from hydronephrosis or renal anomalies with or without stones or secondary infection. The patients in the first group had developmental urinary anomalies. Among them there were 4 who had elevated blood pressures, more than 140 systolic and more than 90 diastolic. These cases give an incidence of 14.2 per cent, which is not greater than that which occurs among the apparently normal population. Persons with renal anomalies are apparently not appreciably more subject to hypertension than are normal people. The patients of the second group were admitted to the Indianapolis City Hospital from five to ten years ago and were chosen because at the time of their first observation their blood pressures were normal, less than 140 systolic and 90 diastolic. Blood pressure elevations did not develop in any of these patients during the interval, although many had had recurrent urinary infections or lithiasis and colic. The author concludes that since neither renal anomalies nor hydronephrosis with or without lithiasis or infection leads to hypertension an increased incidence of pyelographic abnormalities among patients with hypertension might be better explained by the assumption that the humoral substances responsible for hypertension may also act on the kidneys and ureters to produce these distorted shadows.

Electrolyte Changes in Pulmonary Tuberculosis.—Thorn and his associates investigated the blood serum concentration of sodium, chloride, potassium, carbon dioxide combining power and plasma volume of 104 patients with pulmonary tuberculosis in an effort to determine whether adrenal cortex insufficiency existed. Nine healthy men living in the same environment and 7 patients suffering from widespread nontuberculous pulmonary disease (silicosis) were chosen as controls. Because the menstrual cycle has a marked effect on electrolyte balance, only male patients were used for the study. All the patients were provided with an adequate intake of sodium chloride during a preliminary control period. A summary of the observations revealed a significant decrease in serum chloride concentration in patients with pulmonary tuberculosis and in patients with extensive nontuberculous pulmonary disease. The

decrease in serum chloride paralleled closely the decrease in the vital capacity of these patients. The serum bicarbonate concentration of patients with extensive pulmonary disease was increased but it did not equal in magnitude the reduction in serum chloride. There was no significant alteration in the concentration of serum sodium or potassium in either group. The hematocrit (percentage cell volume) of patients with pulmonary tuberculosis and extensive nonpulmonary disease was greater than normal. Blood volume studies and examination of the erythrocytes usually indicated an increase in their number and in their total volume. This was associated with a corresponding decrease in the volume of blood plasma. In 48 of 60 patients with pulmonary tuberculosis, a three day regimen of low sodium chloride intake with supplementary potassium did not precipitate signs or symptoms of adrenal cortex insufficiency. With the exception of a considerable decrease in serum chloride concentration the changes in serum electrolytes, body weight and blood pressure during this period were within normal limits. The urinary concentrations of sodium and chloride on the third day of the test were also within normal range. The appreciable weight loss, the higher than normal urinary concentration of sodium and chloride and the anorexia and weakness which occurred in 2 patients suggested that they may have had some degree of adrenal cortex insufficiency. Patients with pulmonary tuberculosis differed from those with Addison's disease in that they maintained a normal serum concentration of sodium and potassium, preserved a normal total blood volume and withstood a regimen of sodium chloride deprivation with supplementary potassium medication without changes in body weight, blood pressure and urinary concentration of sodium and chloride typically observed in adrenal cortex insufficiency. When acidosis or renal disease is absent the response to the Cutler, Power and Wilder sodium chloride deprivation test is of great aid in differentiating patients with pulmonary tuberculosis from those in whom the pulmonary tuberculosis is complicated by adrenal cortex or anterior pituitary deficiency.

Origin and Nature of Normal Human Synovial Fluid.

—In an endeavor to determine whether the synovial fluid of human beings is a dialysate of plasma containing albumin, globulin and mucin, as is bovine synovial fluid, Ropes and her associates studied the synovial fluid immediately after death of 124 patients who had had no signs or symptoms of joint disease. The study indicated that bovine and human synovial fluids are essentially the same, as the distribution of nonelectrolytes and electrolytes between plasma and normal human synovial fluid were in accord with the observations in normal bovine synovial fluid. Normal human synovial fluid is a dialysate of blood plasma and contains albumin, globulin and mucin. The presence of mucin distinguishes synovial fluid and similar connective tissue fluids from other body fluids that are dialysates of plasma.

Vitamins and Respiratory Infections.—Kuttner studied the effect of adding an excess of vitamins A, C, D and B complex to an average diet of half of 108 rheumatic children from 7 to 14 years of age admitted for institutional care, who remained in the institution from December until the end of May. Children with definite histories of one or two attacks of polyarthritis or carditis without severe cardiac damage were selected. The effect of the addition of the vitamins was studied during two successive winters. Half of the 108 children received

the regular diet with the addition of vitamins, and the other half received the regular diet but were given no additional vitamins. The children in the two groups were matched as nearly as possible as to rheumatic history, age and general condition. Beginning in February 1939 and continuing through May, infections of the upper respiratory track developed in 32 children. These infections were associated with the presence of group A beta hemolytic streptococcus of a single type, type 4. Most of the children complained of sore throat and had temperatures of from 101 to 103 F. for two or three days accompanied by elevated leukocyte counts. Type 4 streptococci were isolated from throat cultures and were usually present in large numbers. Rheumatic manifestations following these respiratory infections did not develop in any of the 32 children. The average gain in weight during the five months for the boys in the two groups was the same. The average weight gain among the girls receiving vitamins was 1½ pounds (0.7 Kg.) more than among those serving as controls. During the winter of 1939-1940 two types of respiratory infections were prevalent among the children: an outbreak of 51 cases of influenza (characterized by fever, malaise and a low leukocyte count) and 24 sore throats accompanied by fever and elevated leukocyte counts. Throat cultures from the influenza cases were negative for beta hemolytic streptococci. Throat cultures from the cases of pharyngitis showed group A beta hemolytic streptococci of a single type, type 27. Of the 13 children who were not receiving vitamins and who contracted type 27 infections a rheumatic recurrence following a latent period developed in only 1. Of the 11 children who were receiving vitamins and who contracted type 27 infections, rheumatic recurrences following a latent period developed in 3. The latent periods were respectively, eighteen, twenty-two and twenty days. The administration of vitamins to these 3 children was never interrupted and therefore the rheumatic recurrence developed in spite of the administration of large amounts of vitamin C. Of the 51 children who had influenza, 26 were receiving vitamins and 25 were in the control group. In contrast to the previous year, the average gain in weight of the boys receiving vitamins was slightly greater than of the control boys and the gain in weight among the two groups of girls was the same. Children receiving institutional care usually tend to gain and therefore no definite improvement can be attributed to the vitamins. No evidence was obtained suggesting that the addition of large doses of vitamins A, B complex, C and D to an ordinary well balanced diet reduces the incidence of infections of the upper respiratory tract.

 *Treatment of Uncomplicated Acute Alcoholism: Preliminary Report on Effectiveness of Insulin, Glucose and Thiamine Chloride in Correcting Pathologic Physiology. G. W. Robinson Jr. and P. Shelton, Kansas City, Mo.—p. 461.

Cold Prevention Studies.—Baker and Cowan present studies on the incidence of colds among university students using amphetamine inhalers or a codeine-papaverine mixture and those employing a placebo for aborting colds at the first onset of symptoms. There were 279 students who used the amphetamine inhaler and 276 who used inhalers except that they contained no amphetamine but in appearance and odor were indistinguishable from those containing the drug. During the two years of the study the amphetamine group reported an average of 1.3 colds per person annually. This represented a reduction of 76 per cent from the average of 5.5 colds per person annually which the same students reported for the two years prior to the study. The control group reported a fall from 5.1 previous colds to 1.9 colds per person annually during the study. This represents a reduction of 63 per cent and certainly nullifies the apparent benefit given by the amphetamine inhaler. There was no difference between the two groups in number of days lost from school. The codeine-papaverine mixture was taken by 224 students and among them there was a reduction of 80 per cent in the average number of colds per person annually during the two years of the study as compared to the two previous years as compared to the reduction of 63 per cent for the control group. The results for the codeine-papaverine mixture, like those for the amphetamine inhaler, are not significantly different. An attempt to summarize the complications of the common cold which occurred during the period of the study, although the number is small, indicates that the codeine-papaverine group presented only about 50 per cent as many complications as the amphetamine group, a previously vaccinated group or the control group.

Treatment of Uncomplicated Acute Alcoholism.—For the last two and a half years Robinson and Shelton have treated their acute alcoholic patients without complicating neurosis or psychosis by correcting the metabolic disturbances by the use of insulin, intravenous dextrose, thiamine hydrochloride and a high caloric diet. One hundred and eighty-six individual patients suffering from acute alcoholism were treated by reestablishing their carbohydrate metabolism; 166 were readmitted, making a total of 352 admissions or patient procedures. Immediately after admission, 20 units of insulin is given and at the first sign of hunger liquid nourishment is provided. If the patient insists on a drink he is given one. The patient must be watched carefully and if the intensity of perspiration increases he is aroused if asleep and urged to take liquids. As an increase in perspiration is evidence of a minor insulin reaction, the patient is usually hungry and cooperative. A second dose of 20 units of insulin is given three hours after the first. This almost invariably produces hunger and the patient will take quantities of liquid food and some may take light solids. After this meal the average patient usually falls asleep and sleeps naturally for several hours. He may wake up nervous and some patients may want alcohol. Shortly after he awakens he is given 500 cc. of a 10 per cent solution of dextrose containing 10 units of insulin and 10 mg. of thiamine hydrochloride. This frequently controls all the nervous symptoms and produces complete relaxation. One or

two subsequent infusions may be given if warranted. Twenty units of insulin is given at 6 and 9 p. m. of the second hospital day, and the patient usually sleeps well this night. The infusion is repeated on the third hospital day, and on this day practically all the symptoms have disappeared. The average requirement of whisky for satisfaction has been about 3 ounces (90 cc.) from admission to the disappearance of all symptoms. Convalescence from this point is uneventful. The authors base this treatment on their belief that alcoholism is a disease with a chronic progressive pathologic background characterized by successive acute pathophysiologic episodes which have primarily a nutritional background. The procedure requires careful, intelligent nursing and medical care if complications (insulin reactions, shocks) are to be minimized. The majority of the patients have liked the procedure, feeling that it has accomplished its purpose quickly and easily, as the fact that so many readmit themselves voluntarily bears out.

Sulfathiazole for Pneumonia in Children.—Scott and Jones report on the treatment with sulfathiazole of 167 infants and children having pneumonia and on 93 treated with sulfapyridine. The usual daily sulfathiazole dose was 1 grain (0.065 Gm.) per pound of body weight. From one fourth to one half of this amount was given as an initial dose, followed by one eighth of the daily dose every three hours throughout day and night and continued until the temperature had been normal for forty-eight hours. Oxygen, transfusion, enemas, measures to combat distention and to secure a free nasal airway, incision of eardrums, aural instillations and sponging were used when indicated. Between Oct. 1, 1938, and June 1, 1939, 58 of the patients treated with sulfapyridine received daily 1½ grains (0.1 Gm.) of the drug per pound of body weight. The remaining 35 patients treated in the fall of 1939 usually received 1 grain. Sulfathiazole seemed to precipitate an early crisis similar in character to the natural crisis to that produced by specific serum or to that produced by sulfapyridine. Usually within twelve hours the fever and toxicity lessened, dyspnea was relieved and the patient began to feel better. In many cases the temperature became permanently normal in twenty-four hours. After forty-eight hours few of the patients had fever and after seventy-two hours only 19 of 158 patients successfully treated had fever. Coincident with the fall in temperature, the child's appetite improved, and activity and responsiveness returned. In a few cases listlessness did not disappear until the drug was stopped in spite of other improvement. Usually physical pulmonary signs improved when the fever abated, but great variability was noticed in this clearing, as it is after a natural crisis. Five of the patients given sulfathiazole died. In the 158 cases in which satisfactory results were obtained, the time between the beginning of treatment and the beginning of a permanent normal temperature averaged 1.8 days. Diagnosis of bronchopneumonia was made

and confirmed by roentgen examination in 18 cases, in which the average days of fever was 1.62, as compared to 1.8 days for the whole group. A study of the time elapsing between the first dose of the drug and the return of temperature to normal of the patients treated with sulfapyridine shows that one cannot infer that there is any superiority of one drug over the other in this respect. Toxic effects following sulfathiazole were largely gastrointestinal, consisting of vomiting and diarrhea, and were mild in comparison with those caused by sulfapyridine. Sulfathiazole is easy to administer to young children and infants.

Duration of Diphtheria Immunity.—Christie presents data of a follow-up study on the lasting effect of seven antigens used for diphtheria immunity. The interval between doses was only one week and the interval after immunization to Schick tests was only three months. The author realizes the discrepancies but believes that they do not minimize the lesson to be learned from an accumulation of such data. Between July 1930 and October 1931 toxin antitoxin was used on 52 children. Three 1 cc. doses of the material were given at weekly intervals. After three months Schick tests revealed that 77 per cent of the children were Schick negative. Nine of this Schick-negative group were retested nine years later and 8 were still negative. Three weekly doses of 1 cc. of toxoid to which 0.5 per cent of alum had been added and contained a flocculating unitage of from 5 to 6 units per cubic centimeter were given 49 children. In three months 93 per cent of these children were Schick negative. Fourteen of them were retested seven years later and 12 (85 per cent) were still negative. Essentially the same material, except for a higher flocculating unitage, was given in two 0.5 cc. doses to 167 children one week apart. Ninety-one per cent of these were Schick negative, while after five and one half to seven years only 52 per cent of the 44 retested were Schick negative. Between August 1932 and April 1934 plain toxoid was given to 87 children with an initial dose of 0.5 cc. followed in one week by 1 cc. After one month 87 per cent of the group had a negative Schick reaction, after five and one half to seven years 8 of the 16 retested had become Schick positive. After one dose of alum-precipitated toxoid 90 per cent of 49 children were immunized but only 46 per cent of 13 retested after five years remained so. Another preparation was given in the same manner to 101 children (one dose of 0.5 cc.) but with a flocculating unitage three and one half times that of the preceding preparation. After six weeks 95 per cent of these children were Schick negative and after four years 75 per cent of 24 negative Schick reactors retested were still negative. Two 1 cc. doses of plain toxoid one week apart produced 94 per cent negative Schick reactors among 94 children in six weeks and after four years 75 per cent of the 24 retested were still negative.

Sulfanilamide Implantation in Clean Surgical Wounds.

—Casberg used sulfanilamide crystals locally as prophylaxis against infection of clean wounds following inguinal herniorrhaphy. Two comparable groups of cases were used as controls. All the operations were performed during December, January and February, as in previous years wound infections were highest

during these months. From 6 to 8 Gm. of sulfanilamide was sprinkled into the subcutaneous tissues between the skin and the aponeurosis of the external oblique muscle. There were no postoperative wound infections among the 18 patients thus treated. Two infections occurred among the 19 patients of one control group and three among 25 of another control group. Three of the infections were due to *Staphylococcus aureus* and 2 to *Streptococcus haemolyticus*. The absence of wound infection following local sulfanilamide implantation does not obviate any of the operating room rules of asepsis.

Zinc Peroxide for Surgical Infections.—Gius reports four cases in which zinc peroxide was used with good results in three, while the fourth illustrates a hazard of introducing zinc peroxide or similar material into a closed cavity. In the first three cases the infection was localized to the parietes, but in the fourth case it was confined to the pelvis and zinc peroxide could be introduced only by injection through the colpotomy wound. The zinc peroxide suspension passed through the wall of the abscess and into the peritoneal cavity, resulting in diffuse peritonitis. Fortunately, the patient recovered and has apparently been cured.

Epidemic of Acute Infectious Jaundice.—Learn discusses sixty-two instances of epidemic acute infectious jaundice encountered in his private practice. The cases began to appear in September 1937 and continued to March 1938; no more cases were observed until September 1938, when the epidemic again became prevalent and lasted until March 1939. Since that time only three cases have been observed. Most of these cases were mild and ambulatory; the greatest number occurred in children from 6 to 8 years of age. The youngest patient was 3 and the oldest 47 years of age. The severity of the illness usually increased with the age of the patient. The incubation period was two weeks in most of the cases. As many as six cases occurred in one family, but not all the exposed children were affected. Clinical evidence shows that the disease is transmitted from person to person and that most adults are immune. There were few complications and only one death in the author's series. Epigastric pain, nausea, fever and tenderness in the upper right quadrant occurred in all the cases, vomiting in forty-seven, bile in the urine in thirty-six cases, clay-colored stools in eighteen and epistaxis in twelve. A spirochete which resembles *Leptospira* was isolated in a sufficient number of the cases to determine that it was the cause of the epidemic. In two of the three

cases in which there was a recurrence of the jaundice the dark-field examination was positive. In one of these the spirochetes were recovered from the macerated kidney substance of an inoculated guinea pig.

Institutional Outbreak of Pneumonitis.—According to Hornbrook and Nelson, 15 cases of pneumonitis occurred during the spring of 1940 among the 153 employees in one building of the National Institute of Health. The roentgenograms of the cases showed one or more pneumonic shadows. There were a few other cases of a somewhat similar but milder type which gave no roentgen signs or roentgenograms were not obtained. The onset was fairly sudden though usually not severe. Two types of onset predominated, one coryza-like, the other with headache, chilly sensations and general malaise. There was a latent period of about three days following the onset in which the patient continued to work although feeling ill. Severe and persistent headache was a prominent symptom developing during the latent period. In none of the cases was a "prune juice," rusty or blood-tinged sputum observed. Approximately half of the patients developed vague neuralgic chest pains in the substernal region or on the side of their demonstrated pulmonary lesion. All the patients complained of insomnia. There were no physical abnormalities on physical examination; in fact, their absence was one of the characteristics of the disease. On admission the average pulse rate was 99 beats and the average temperature was 102.4 F. (varying from 100.5 to 104.5 F.). The pulse rate did not always parallel the temperature curve. The roentgen examination gave the most typical and consistent evidence of pulmonary lesions. A soft infiltrative lesion, single or multiple, was visible on the films but was not of the uniform density seen in lobar pneumonia. The lesions appeared to be more of the patchy type seen in bronchopneumonia. It is doubtful whether many of the patients would have been considered as having a pneumonic process without roentgen examination. Blood cultures, agglutination tests, using *Eberthella typhi*, *Brucella abortus*, *Bacillus proteus* OX19 and *Pasteurella tularensis* as antigens, and sputum studies for pneumococci were negative. The usual supportive hospital treatment was given all the patients. Other than 1 death there were no serious complications. Dyer and his co-workers isolated the etiologic organism, the rickettsia of Q fever, from 3 of 4 of the epidemic cases in which it was attempted. From various reports by other workers it seems possible that this disease has had a widespread geographic distribution; the cases of these other outbreaks have been reported as bronchopneumonia of unknown etiology (variety X), atypical pneumonia and atypical bronchopneumonia. The clinical course of these outbreaks and of the epidemic under discussion was consistent. The three strains isolated gave cross immunity to one another, to strain of American Q fever previously reported from the laboratory of the National Institute of Health as "strain X" and to a strain of Australian Q fever received from Burnet. Dyer and his co-workers point out that no valid evidence was adduced that personal contact or the intervention of an arthropod vector was responsible for the transmission of the disease. Strains of Q fever have been carried in animals and tissue cultures in one unit of the National Institute of Health since 1938. Whether or not this unit served as a source of infection is open to question, since the personnel of the unit was spared and the cases were widely distributed throughout the building.

Body Build and Drug Addiction.—Brown made anthropometric studies of 400 native white male adult addicts following their admission to the United States Penitentiary Annex, Fort Leavenworth, Kansas. The cases represented consecutive admissions, the only selecting factors being those of color, nativity and verified history of drug usage. Measurements were taken on unclothed patients according to the technic of Hrdlicka. Subjective estimates were made also of the face shape, face profile, conformation of head, baldness, neck, trunk profile, general appearance as to nutrition, skin color, musculature, dysplastic traits and estimate of body type. On the basis of the investigation the narcotic drug addicts of the study were average or slightly superior in height and weight. There was an average gain in weight of a little more than 3 Kg. (6½ pounds) after five and a half months of institutionalization. The body build of the group was found to be within normal limits with a trend toward the pyknic end of the distribution. The drug addiction of the group could not be ascribed to gross constitutional weakness.

Diagnosis of Renal Tuberculosis.—Emmett points out that in the diagnosis of renal tuberculosis the trend is away from retrograde pyelography and toward excretory urography. There are only four methods of investigating a kidney in the presence of tuberculous disease, and all may give negative results even though tuberculosis is present. These methods are urography, determination of pus corpuscles in a "wet smear" of urine obtained by ureteral catheterization, microscopic examination of a stained specimen of ureteral urine for acid-fast bacilli, and inoculation of guinea pigs with a catheterized specimen of urine. All these examinations except descending urography require cystoscopic investigation. More than one cystoscopy may be required to make all of them. Cystoscopy carried out in the presence of urinary tuberculosis is usually a painful procedure unless anesthesia is employed. Repeated cystoscopy is not only painful but it may traumatize infected tissue. Only those examinations should be employed which enable one to arrive at a sound diagnosis. The ultimate in diagnosis in renal tuberculosis is the minimal amount of investigation that will permit a diagnosis sufficiently accurate to suggest correct treatment. One brief cystoscopic examination should be sufficient in each case. Repeated instrumentation is to be avoided. The excretory urogram will indicate the involved kidney in most cases and it is accurate in this regard. The excretory urogram will suggest the condition of the uninvolved kidney, but this information is inaccurate and must be supplemented by an examination of a ureteral specimen of urine, by microscopic examination of the wet smear, special staining methods for acid-fast organisms and inoculation of guinea pigs with specimens of urine. Retrograde pyelography is rarely necessary for the involved kidney but is occasionally necessary for the uninvolved kidney when the excretory urogram is poor. Routine bilateral pyelograms are entirely unnecessary and are not in the interest of the patient either economically or physically. They may be necessary in a small group of cases in which the diagnosis is in doubt. The results of nephrectomy in 1,131 cases of renal tuberculosis performed at the clinic between 1912 and 1932 indicate that the term "unilateral" renal tuberculosis is not justified. They demonstrate that the more nearly "normal" the uninvolved or the least involved kidney is proved to be, the better will be the clinical results following removal of the involved kidney. The results of nephrectomy in grossly bilateral renal tuberculosis are not good and do not justify its performance on the belief that removal of the worse kidney may relieve the vesical symptoms. Of 718 cases in which the specimen of urine from the uninvolved kidney contained no pus corpuscles, 65.2 per cent of the patients were either cured or improved at the end of five years and

56.4 per cent at the end of ten years. Among these cases there were 55 in which inoculation of guinea pigs with urine gave positive results, and only 36.4 per cent of these patients were cured or improved at the end of five years and only 30 per cent were alive at the end of ten years. The best results were obtained among 209 patients in whom no pus corpuscles were being excreted from the uninvolved kidney and the results of inoculation of animals with specimens of ureteral urine were negative. At the end of five years 75.2 per cent of the patients were cured or improved and at the end of ten years the percentage was 65.5.

Blood and Lymph Vessel Tumors.—Watson and McCarthy made a study of 1,056 patients with 1,363 benign lymph and blood vessel tumors admitted to the Memorial Hospital during 1931 to 1939. There were 1,308 hemangiomas, 41 lymphangiomas and 14 hygromas. Seventy-three per cent of the patients presented evidence of tumor at birth and 85 per cent developed before the end of the first year. The authors propose a classification based on clinical, pathologic and therapeutic considerations: capillary hemangioma, cavernous hemangioma, angioloblastic or hypertrophic hemangioma, racemose hemangioma, diffuse systemic hemangioma, metastasizing hemangioma, naevus vinosus or port wine stain, and hereditary hemorrhagic telangiectasis (Rendu-Osler-Weber disease). Solid carbon dioxide was satisfactory for superficial capillary lesions and for clearing the residual mottled areas remaining after sodium morrhuate therapy. Sodium morrhuate injection was most effective for simple cavernous and stellate hemangiomas and for Rendu-Osler-Weber disease. Solid carbon dioxide and sodium morrhuate were used together or combined with radiation. External radium brass applicators were especially applicable for capillary hemangiomas that were too thick for solid carbon dioxide therapy and also for superficial small cavernous hemangiomas resistant to sodium morrhuate. Interstitial irradiation, radon-filled, hollow 4 mm. gold seeds, was reserved for the most resistant hemangiomas and was especially well adapted for thick, bulky capillary or cavernous hemangiomas requiring skin damaging doses of external radiation. Gold radon seeds were employed for rapidly growing hemangiomas resistant to sodium morrhuate and as an adjunct for racemose angiomas. The end results obtained with high, medium and low voltage roentgen rays were disappointing. However, high voltage roentgen therapy seems indicated for osseous, large hepatic cavernous hemangiomas, hemangiomas of joints, synovia, inoperable extensive muscle angiomas and certain racemose hemangiomas. There is no successful treatment for metastasizing hemangioma. More good regressions were obtained in infants less than 3 months of age than in those more than 6 months of age. Radiation measures are hazardous and should be used with caution for hemangio-

mas of the scalp, midline areas over the sternum or vertebrae, breasts, genitalia, long bones, lips and areas adjacent to the eyes. Surgical excision is indicated for the small papillar tumors, bulky capillary lesions in areas where scars may be concealed, the resistant angioliomas, muscle hemangiomas and angiofibromas. Port wine stains do not respond well to radiation, solid carbon dioxide or sodium morrhuate. Small lesions may be excised, but larger ones can be improved cosmetically only by covering them with cosmetic paste. The percentage of good results for surgical excision was 91, for solid carbon dioxide 88, for sodium morrhuate 86, for a combination of the latter two measures 86, for combined radiation and physical methods 65, for external radon radiation 61, for interstitial radon radiation 59, for "x-radiation" 48 and for combined radiation 57. Lymphangiomas, like hemangiomas, may possess marked growth capacity and are not, as was once supposed, dilated, static, normal lymph channels. Of the 41 lymphangiomas 61 per cent were present at birth and 95 per cent were observed before the age of 10. The lymphangiomas have been classified into five divisions: simple, cavernous, cellular or hypertrophic, diffuse systemic lymphangiomas and cystic hygroma or the cystic lymphangioma. The tumor definitely develops from lymphatic tissue in the neck, axilla, retroperitoneal tissues or groin. Hygromas are generally present at birth and grow rapidly. Thirteen of the 14 tumors were located in the neck and the other one in the axilla. Wide surgical excision affords the best prognosis in the treatment of lymphangiomas despite unsightly scars and postoperative keloids. The operative results were good in 77 per cent of 13 patients. Lymphangiomas are radioresistant. However, irradiation is the method for diffuse systemic lymphangiomas which affect an entire extremity. Sodium morrhuate injections have no effect on lymphangioma, with the exception of cystic hygroma. Seventeen lymphangiomas recurred. Cystic lymphangiomas (hygromas) are relatively radioresistant. Surgical excision was performed in 7 cases with a good result in 5. Sodium morrhuate should be tried for all hygromas and if it fails, surgical excision should be tried, and if excision is incomplete then irradiation may be attempted.

Acute Intestinal Obstruction.—Mayo and his associates point out that the mortality from acute intestinal obstruction continues despite improvements in surgical technic and added therapeutic aids. Bands and adhesions, congenital or inflammatory, are second only to external hernias as causes of intestinal obstruction. Twenty-four patients suffering from acute intestinal obstruction as a result of bands and adhesions were seen at the Mayo Clinic from 1935 to 1939, during which time 136 cases of acute intestinal obstruction were encountered. Of these 136 cases 81 were due to external hernias. Internal hernias as a result of abdominal operations are less frequent, owing to operative precautions, such as the suturing of the stomach to the opening in the transverse mesocolon when posterior gastro-enterostomy is performed. The more important internal hernias at present are those resulting from congenital defects. Seven cases of internal hernias and acute intestinal obstruction were seen at the clinic during the five years under consideration. Volvulus of various portions of the intestinal tract accounted for only 9 acute intestinal obstructions. Intussusception accounted for 10 cases; 8 of the patients were 2 or less years of age, 1 was 4 and 1 was 6. Three of the cases were caused by mesenteric thrombosis, 2 were due to gallstones, 2 to congenital mesenteric cysts, 2 to diverticulitis and 4 to carcinoma. Simple mechanical obstructions of the small intestine early in the postoperative period in which strangulating lesions can be eliminated respond well to decompression of the intestine by the Wangenstein method. This is not true for obstructions of the small intestine caused by bands and adhesions in the late postoperative period. Analysis of the results of this group reveals a high incidence of strangulation. Signs indicative of strangulation must be watched for and, if not present, conservative treatment may be employed. Colonic obstruction must be considered a strict contraindication to the use of suction drainage. Cecostomy or colostomy is the procedure of choice and does not carry an elevated risk in comparison with "blind" intubation. When operation is indicated, the most conservative procedure possible under the exist-

ing circumstances should be employed after the patient has been properly prepared. When resection is necessary, the loop should be exteriorized and the continuity of the intestine restored later when the patient is in better condition. Primary resection with closure of the intestine and side to side anastomosis is too hazardous a procedure unless performed for a small lesion high in the intestine. Useful postoperative therapeutic adjuncts are blood transfusions and 100 per cent oxygen. There is a correlation between the duration of obstruction or strangulation and the mortality rate. The combined mortality among the 136 patients was 22 per cent and of the patients who died about half had been ill for more than forty-eight hours before coming to operation and an additional 3 had been ill about forty-eight hours. The adverse effect of delay in recognizing and treating strangulating lesions is especially true in obstructions caused by bands and adhesions in the late postoperative period. The prophylactic repair of hernias in suitable cases will reduce not only the incidence of obstruction but also the resultant mortality rate.

Tests Estimating Bleeding Tendency in Jaundice.—Ferguson and his associates performed simultaneously the Ivy bleeding time test, the serum volume test of Boyce and McFetridge and the Quick method of determining the prothrombin content of the blood. The estimations were made from the same specimen of blood drawn from each of 27 jaundiced patients. The jaundice was due to various causes. The authors find that there is sufficient correlation between the tests to warrant confidence in the use of the two simpler tests as adjuncts to or substitutes for prothrombin studies or when laboratory facilities for prothrombin determination are not available. A blood prothrombin level of 30 per cent or less was selected arbitrarily as a level at which danger of bleeding due to prothrombin lack was imminent. Of nine determinations in which the prothrombin percentage was 30 per cent or less either the Ivy bleeding time or the serum volume index or both indicated a definite bleeding tendency. In 2 cases in which the prothrombin percentage was respectively 33 and 50 per cent, a definite hemorrhagic tendency was suggested by the Ivy bleeding test, the serum volume index and clinical evidence of bleeding. In a third case with a prothrombin determination of 30 the serum volume index was 0.76, not indicative of a bleeding tendency, though the Ivy bleeding time was ten minutes. In none of the cases with a prothrombin percentage above 30 was there clinical evidence of bleeding. Seven of these patients showed a serum volume index between 0.7 and 0.8 and in 3 of these the Ivy bleeding time indicated a bleeding tendency and in 1 the serum volume index was reduced to a definitely critical level. However, in no case did both tests indicate a definite hemorrhagic tendency, although in 2 with the Ivy bleeding time prolonged the serum volume index was between 0.7 and 0.8. Therefore either one or both of the two simple tests showed the tendency to hemorrhage in cases in which it was indicated by the blood prothrombin level. In 2 cases both tests indicated the hemorrhagic tendency in agreement with the clinical evidence, while the prothrombin percentage did not. In 4 cases one or the other of the simpler tests indicated a hemorrhagic tendency when there was no other evidence that it existed.

*Action of Acetylsalicylic Acid on Teeth. D. B. Dott.—p. 700.

Action of Acetylsalicylic Acid on Teeth.—Dott found that strong solutions of acetylsalicylic acid extract calcium from teeth. His observations leading to this observation were as follows: He dissolved 5 grains (0.32 Gm.) of acetylsalicylic acid in 1 ounce of distilled water at about 140 F. The solution was poured on four teeth in a 2 ounce bottle. This was gently rotated and the solution was quickly filtered after five minutes, and then ammonia and ammonium oxalate were added. There was an immediate white cloudiness soon settling as a definite precipitate. The teeth used appeared normal and free from carious matter. The experiment was repeated and the solution was left in contact with the teeth for ninety minutes before filtering and precipitating. The washed oxalate was dried and strongly ignited in a porcelain crucible, and the resulting calcium oxide weighed 0.011 Gm. (0.17 grain). In several other experiments it was found that the loss of weight of the teeth after the action of acetylsalicylic acid was much greater than the weight of calcium oxide obtained. By dissolving equal weights of acetylsalicylic acid and sodium bicarbonate, one obtains a faintly alkaline solution which has no appreciable action on teeth. The author points out that the question as to how far these facts should limit the use of acetylsalicylic acid as a mouth wash is for medical decision.

Cerebrospinal Meningitis.—The only effective prophylaxis, according to Mutch, against cerebrospinal meningitis consists in free ventilation and the avoidance of overcrowding. Since the survival time of the isolated meningococcus is short, the disease can be contracted only by close association with some one already infected. It was found that the carrier rate of infection could be reduced in dormitories to 5 per cent by spacing beds 3 feet apart, compared with a 20 per cent rate in 1 foot bed interspacing and a 29 per cent rate in a 9 inch bed interspacing. In the treatment of cerebrospinal meningitis, lumbar puncture and antimeningococcus serum have been replaced by sulfanilamide and sulfapyridine with marked results. Here the superiority of one drug over the other has not yet been determined. In 5,306 cases notified during the war years of 1914-1918 mortality was as high as 65 per cent; in 5,093 cases reported for the first six months of 1940 the death rate was only 20 per cent. Lumbar puncture is performed only at weekly intervals or when definite signs of increased intracranial pressure are observed. The dosage, administered in approximately equal quantities for the two drugs, ranged from 3 Gm. in infants to 9 Gm. in adults (down to 15 years) and was given daily for a week in six doses spaced four hours apart in order to maintain a uniform concentration in the body tissues but allowed for adjustments in severe attacks with supplementary intravenous

injections of soluble sulfapyridine. Comatose patients were given the drug in powdered form in suspension through a stomach tube. Intramuscular injections were found impracticable for a number of reasons. In view of the frequent occurrence of adrenal hemorrhage in cases of septicemia rapidly terminating fatally, vitamin C, citrus fruits and adrenal cortex extract are tentatively suggested as means of saving life. Since rapid dehydration occurs in unconscious pyrexial patients, a copious fluid intake is recommended either by stomach or by rectal tube or by an intravenous drip of dextrose-saline solution. The author discusses the nature of the infective organism, its path of invasion, the spread of the infection, the clinical varieties of the disease and complications such as the common occurrence of arthritis. A preparation that is inexpensive, soluble and susceptible of being administered rectally to unconscious patients or to those with troublesome cerebral vomiting is a desideratum.

Insulin Substitutes.—Luntz summarizes present day knowledge of insulin substitutes. All of these aim at curing or alleviating diabetes by oral administration. However, no remedy replacing insulin for pancreatic dysfunction has yet been found. The use of substitutes not only delays initiation of proper medication but invites the progress of the disease to a dangerous stage. Improvement attributed to the oral use of substitutes is, in reality, due to the strict regimen imposed on the patient, as various investigations have shown. Substances employed as substitutes or experimented with include guanidine derivatives, succinic acid, a decoction of the kadal ranji root, a hypoglycemic extract of the roots of the "devil's club," duodenal extracts, vegetable protein preparations, protein injections and cabbage extracts. Guanidine derivatives are synthetic compounds with an effect resembling that of insulin. Used on the continent they have been found by British investigators to be impracticable and even dangerous. A continental product (synthalin), a decamethylene diguanidine hydrochloride and reported to lower blood sugar, did in some cases lower ketosis in the urine but also exhibited toxic properties by inducing gastrointestinal disturbances in many patients and jaundice and hepatitis in others. Synthalin is a harmful drug, as it lowers the blood sugar not by promoting increased oxidation of dextrose but by a toxic effect on the liver. Neosynthalin, containing fourteen methylene groups, appears to be less toxic and perhaps not so active as the original product. Succinic acid, orally administered for the control of diabetic ketosis, in the hands of English and Scotch analysts either gave negative results or failed to prevent the onset of diabetic coma or to diminish chronic diabetic ketonuria. Györgyi, its author, proceeded on the assumption that the C₄ carboxylic acids, especially pyruvic acid, played a vital part in intermediate carbohydrate metabolism and that ketosis represented a dysfunction of these acids and could be prevented by succinic acid (obtained from amber, COOH.CH₂.CH₂.COOH, containing four carbon atoms) acting as a catalyzer. The kadal ranji root decoction popularly used by Indians for diabetes, renders the urine of diabetic subjects sugar free by raising the renal threshold for the excretion of sugar. It is considered dangerous by its author. Investigations of the hypoglycemic substance inherent in the extracts from the devil's club root (*Fatasia horrida*) and ostensibly nontoxic is being further investigated. Duodenal extracts, first used in 1939, failed to give uniform clinical results. The extract varied in different cases, not in relation to the actual severity of the case, but rather to the duration of the disease. A diminution of hyperglycemia, glycosuria and diuresis and an increase in weight were noted. A vegetable protein preparation derived from the germ of the carob or locust bean (*Ceratonia siliqua*) and tried out on diabetic children yielded inconclusive results. Protein injections prepared by G. Singer merit further consideration, though his view that they form the basic treatment of diabetes cannot be accepted. The mechanism of action is by no means clearly understood. The effect on diabetes may be due to their power of modifying metabolism. Experiments with cabbage extracts on blood sugar concentration, with which MacDonald and Wislicki experimented on animals, chiefly rabbits, to discover a preparation devoid of toxic effects, yielded them both a hyperglycemic and a hypoglycemic fraction. The latter was effective orally as well as when injected and no hypoglycemic convulsions

were evoked. In a depancreatized dog which had been kept alive by injections of insulin, blood sugar and glycosuria were controlled by the sole use of this extract and insulin could be withdrawn entirely. A two day interval between withdrawal of the cabbage extract and resumption of insulin therapy was marked by an abrupt rise in the concentration of dextrose in the blood and urine. According to Luntz the specificity of insulin in the successful management of diabetes should constantly be emphasized against the proponents of all irrational medicines and therapies until a better remedy has been found. Synthetic products so far evolved cannot compare with insulin in efficacy and are of little if any use in the practical treatment of diabetes. The ultimate conquest of diabetes may depend on a more thorough understanding of carbohydrate metabolism. That implies a better understanding of the anterior pituitary, the adrenal cortex and various other active agents in the body.

Strangulated Inguinal Hernia in Infant.—Gordon reports the rare case of strangulation of congenital hernia in an infant aged 5 weeks, the third child born of a normal mother aged 26. At birth the mother had noticed a lump in the right groin, which, however, had disappeared a week later. The reappearance of this lump under circumstances of aggravated screams, bile-stained vomiting and attacks of colic caused the child to be hospitalized. The lump was found to be red, tense and irreducible. No right testis was found. The abdomen was distended with visible coils of intestine but with no visible peristalsis. There were no feces in the rectum. When the inguinal canal was opened a tense hernial sac was encountered, containing about 8 inches of blue ileum, 1 inch of which was plum colored. A tough constriction of the internal inguinal ring was divided, but as the child began to cry no resection of the intestine was attempted and no repair operation done to strengthen the inguinal sac. The child was given 20 ounces (600 cc.) of saline solution by subcutaneous drip during the first twelve hours after the operation and was then breast fed. The child continued to feed normally, no longer vomited, recovered stool action and was discharged six days later.

Roentgenography in Postoperative Ileus.—Ascroft and Samuel report a study of radiologic diagnosis of intestinal obstruction. Of 75 cases treated, 18 belong to the postoperative group; in most there was peritonitis, and symptoms developed of the type of ileus usually called paralytic. The plain roentgenograms were a great help in assessing individual cases. Whenever the abdomen is opened, the motility of the gastrointestinal tract and, to a lesser extent, its secretory and absorptive capacity are disturbed, producing adynamic ileus. This

condition is nearly always transient, subsiding in from six to twelve hours, and needs no special treatment; but, when there is peritonitis, especially if it is due to bacteria, adynamic ileus persists, and the abdomen may become greatly distended. All the signs of intestinal obstruction are present save one: there is no peristalsis. This makes diagnosis easy and obviates an attempt to relieve an "obstruction" by operation. The same applies to the rare instances of severe and persistent adynamic ileus uncomplicated by peritonitis. However, most cases causing anxiety after operation are not of this type. The authors show that most cases of postoperative ileus causing anxiety are due either to focal obstruction at the line of suture or, more commonly, a diffuse or peritonic obstruction. Plain roentgenograms give evidence of obstruction in both types of case. In 5 cases of suspected focal obstruction, roentgenography excluded obstruction, no operation was performed and recovery occurred. In 9 cases of peritonic obstruction, roentgenography demonstrated obstruction of the small intestine. In cases of obstruction, plain roentgenograms taken in the erect position show distention of the small bowel with fluid levels in the distended loops. In cases not requiring immediate operation intestinal drainage by suction through a duodenal or Miller-Abbott tube should be combined with serial roentgenography. Reliance on clinical signs alone may lead to dangerous delay, but roentgenography will show whether the obstruction is persisting.

Sulfathiazole in Pneumococcal Lobar Pneumonia.—Gaisford and Whitelaw employed sulfathiazole in a series of pneumococcal lobar pneumonias and sulfapyridine for alternate patients as controls. Ten patients with true lobar pneumonia were treated with sulfathiazole. There were no deaths and only 1 patient had a complication, an empyema which was drained, with recovery. Among the 9 patients who were treated with sulfapyridine there likewise were no deaths, but 1 patient developed a sterile serous effusion. Sulfathiazole acts similarly to sulfapyridine, but it produces a less prompt fall in temperature. With this temperature lag there is a correspondingly longer period of acute illness. This renders sulfapyridine the drug of choice in severe cases. The chief point in favor of sulfathiazole is that it does not cause vomiting. It is possible that a combination of sulfapyridine and sulfathiazole may come to be a valuable routine in the treatment of pneumonia, the first large doses given being sulfapyridine (e. g. the first 8 tablets) and the following ones sulfathiazole. In this way vomiting can be obviated entirely. An alternative is the use of a mixture of the two drugs from the outset, e. g. 2 tablets of sulfapyridine given with 2 tablets of sulfathiazole four-hourly for the first three doses and then one tablet of each. The first method has already been used since these investigations were undertaken with satisfactory results.

Abdominal War Wounds. T. Naegeli.—p. 894.

Secondary Effects of Sulfapyridine.—Heggin reports the secondary effects observed in connection with the use of sulfapyridine in more than 450 cases of pneumococcal, meningococcal and gonococcal infections, with granulocytopenia (1 case, terminating fatally) and grave hematuria (5 cases) ranking as the worst effects. Nausea, vomiting, hematuria, mild anemia, cyanosis and cutaneous manifestations (3 per cent) were observed almost regularly. Latent and slowly developing granulocytopenia manifested itself suddenly in a patient with unilateral pneumonia, with high fever, though the drug had been discontinued for some time and the patient felt completely well. Renal lesions were disclosed in grave hematuria, in 1 case evolving into anuria, with increased residual nitrogen. Hematuria often presented a clinical picture of a pronounced renal colic due to calculus, an intense pain extending from one or both kidneys into the testicles and involving only a mechanical lesion, leaving the glomeruli unaffected. Copious water ingestion, regarded by the author as a necessary therapeutic adjuvant in renal stone due to the drug, released large quantities of gravel, acetylsulfapyridine forming the chief constituent. The author believes that, though grave secondary effects cannot be avoided because of the relatively high doses required for treating pneumonic infection, sulfapyridine has proved its chemotherapeutic value. However, the possibility of untoward effects should constantly be borne in mind in order that appropriate counteractive measures may be duly employed. Secondary effects of a nonserious nature, such as nausea and vomiting, may acquire so pronounced an intensity as to necessitate discontinuation of the drug and thus jeopardize the patient's chances of recovery. Granulocytopenia induced by sulfapyridine is not necessarily fatal. An erroneous diagnosis would see in the clinical picture a reactivation of the infection and resume the use of the drug, whereas, in reality, blood analysis would show that damage had been done to the bone marrow. Hematuria ought not to be lightly regarded, as it may lead to anuria. When anuria has set in, cystoscopy is urgently indicated. Sulfapyridine, though parenterally given, was found excreted in the gastric juice, in one case with a 30 per cent concentration. No injurious secondary effects were noted on the nervous system.

Sulfathiazole in Epidemic Cerebrospinal Meningitis.—Pulver found sulfathiazole effective in epidemic cerebrospinal meningitis. Of 26 patients treated solely with this drug (their age level ranged between 1 and 61 years [19 under 16 years]), all recovered save 2, thus yielding a mortality rate of 6.9 per cent compared with a 50 per cent death rate previously noted during a ten year period. Cerebrospinal fluid tests disclosed *Neisseria meningitidis* in 23 of the cases and its subsequent disappearance within three to seven days after medication. (Nasal and pharyngeal smears had detected the micro-organism in only 2 cases.) Blood tests showed in individual cases a decrease in the leukocyte count from 24,800 and 30,200 to 5,800 and 6,700 leukocytes respectively within two days. Biochemical analyses made at regular intervals disclosed a rapid return to normal levels in the sugar, total albumin and chloride content of the blood. The author's experiments in reducing dosage to the lowest quantities compatible with therapeutic effects were finally stabilized at from 12 to 20 Gm. within four to seven days, but allowing for increased dosage in complications. Initial doses in adults of from 1 to 2 Gm. and in children of from 0.1 to 0.15 Gm. per kilogram of body weight and totaling from 6 to 8 Gm. within twenty-four hours were reduced after defervescence to one third and one half of the original dosage. In the majority of cases these quantities of the drug were able to lower fever of 100.4 to 104 F. to subfebrile or normal conditions within twenty-four to forty-

eight hours. In order to prevent reactivation the drug was continued for several weeks more. Among the significant effects reported by the author is the observation that some of the children and adults brought to the clinic in a semi or total state of unconsciousness in the morning were able to play in their beds or read the newspaper in the evening. However, headache and cervical rigidity tended to linger for from two to ten days. The drug was administered intramuscularly, in exceptional cases intravenously with dextrose, and caused no local inflammation. Its superior atoxicity was seen in the absence of such secondary effects as granulocytopenia, hemolysis, hepatic lesions, renal irritation and grave cyanosis. A stubborn case of granulocytopenia in a boy aged 8 years with final recovery and a case of neuritis with metastatic acute arthritis of the knee joints are cited by the author as the only evidence of toxic damage produced by the drug. No intraspinal injection was practiced. The drug was found efficacious even in cases of seriously delayed medication.

Sulfathiazole as Chemotherapeutic Agent in Gonorrhea.—Miescher reports the cure of 14 out of 15 male patients, mostly with uncomplicated gonorrhea, by means of a single peroral dose of sulfathiazole. The massive dose, varying between four and ten tablets of the drug (tablet 0.5 Gm.), was either mixed with sugar and placed on the tongue in powdered form or dissolved in water and ingested in 0.5 liter of a native tea. No untoward effects nor relapses were observed. The single dose therapy represents an experimental evolution first from favorable results obtained by combining local and intramuscular vaccines with sulfathiazole for the cure of acute and chronic gonorrhea and then from the exclusive use of sulfathiazole spread over a progressively diminishing period of time. In these experiments the author had observed a reduction in gonococcus count and in gonorrheal discharge usually twenty-four hours, frequently also even twelve hours after medication. Single doses of ten tablets (5 Gm.) are regarded by him as approximating highest levels of tolerance.

Eupaptic and Carminative Substances: Clinical Researches for Effects. A. Bellomo and R. Bologna.—p. 217.

*Immediate Action of Liver Extracts on Reticulocytogenic Power of Gastric Juice. G. Lami.—p. 223.

Effect of Liver Extract on Reticulocytogenic Power of Gastric Juice.—Lami studied the reticulocytogenic effect of the gastric juice of 15 normal persons and of 10 patients with pernicious anemia for an hour and a half following intravenous injection of 5 cc. of a liver extract of high potency ("Hepracton"). The gastric juice was removed during fasting and after an injection of histamine alone or preceded one hour earlier by a meal of 100 Gm. of meat. Singer biologic reaction was used to determine the reticulocytogenic power of the gastric juice. The test consists of injecting subcutaneously 3 cc. of neutralized filtrates of the gastric juice to male adult white rats in which the number of reticulocytes is determined before the test. The reticulocyte curve is followed every day for one week. The filtrates can be prepared from the mixture of three or four samples of the gastric juice withdrawn at intervals of fifteen or thirty minutes after the histamine injection following the injection of liver extract alone or preceded by a meal of meat or with the separate samples of the gastric juice. A positive reaction is manifested by an increase in the percentage of the reticulocytes in the blood of the animals and indicates the presence of the antianemic principle in the gastric juice. Failure to change on the part of the reticulocytic curve indicates a negative reaction and absence of the antianemic principle in the juice. The highest figures in the reticulocyte curve occur on the second, third or fourth day of the test, which gives a positive result in normal persons and in achylic hypochromic anemia and negative results in pernicious anemia. The positive results agree with those of the Castle test. In the cases observed by the author the reticulocytogenic power of the gastric juice of normal persons was increased after the injection of the liver extract (strong positive results of the Singer test). The increase was greater when the test included a meal of meat than when it did not. The reticulocytogenic power of the gastric juice of

patients with pernicious anemia in remission from liver therapy was greatly diminished before administration of the liver extract (weak positive results of the Singer test) and did not change after administration of the extract. The gastric juice of patients with pernicious anemia who had not had liver therapy did not possess reticulogenic power before administration of the liver extract (negative results of the Singer test) but increased after administration of the extract. The author believes that liver extract injected intravenously stimulates the absorptive capacity of the gastric wall and upper segment of the intestine for the antianemic principle and stimulates the production of the endogenous factor which results in a better use of the exogenous factor and consequent production of the anti-anemic factor. The latter, as soon as it is stored in the liver, stimulates the gastric wall and the upper segment of the intestine to further production of exogenous factor and to hemopoiesis. Liver extract injected intravenously acts through a mechanism of stimulation. It acts as substitution therapy only when the gastric wall and intestine are the seat of grave pathologic lesions.

Vitamin Therapy in Otosclerosis.—Baer reports unsuccessful results in experiments undertaken to modify otosclerosis in 15 cases by means of vitamins C and B₁ and a regimen rich in these vitamins, employed for several months at a time. Subjective symptoms such as headache, vertigo, anorexia and tinnitus aurium were favorably affected and the improvement credited to vitamin B₁. The author encountered a vitamin C impairment of from 600 to 1,500 and even 2,000 mg. but does not believe in a direct connection between general vitamin C deficiency and otosclerosis. Irrespective of the vitamin C index, he fed vitamins in concentrated doses to all otosclerotic patients on the assumption that a local vitamin deficiency may well coexist with a systemic sufficiency, as is seen in parodontosis, in which the osseous changes resemble those of otosclerosis and even permanent cures seem to be effected by vitamin C. He inclines to the view that otosclerosis represents a new bone growth and hence an osteitis fibrosa, which may be hereditary in some cases. The general ineffectiveness of therapeutic measures to influence otosclerosis justifies any rational experimentation. Besides, vitamins ineffective in relation to the otosclerotic process may increase the efficacy of other medicaments employed to influence the pathologic process.

Malignant Exophthalmos After Strumectomy.—Jensen describes four cases of exophthalmic goiter in which malignant exophthalmos developed after strumectomy. Malignant exophthalmos is characterized by a rapid and violent progression. In the beginning the patients complain only of conjunctival discomfort due to smarting pain, injection and profuse epiphora. These symptoms become manifest several months after a successful strumectomy which led to the disappearance of all hyperthyroid symptoms with the exception of ocular proptosis. Then there appear peculiar pasty thickenings of the eyelids and of the integument surrounding the eyes and pronounced chemosis with coincident aggravation of the bulbar protrusion. Violent headache develops and a painful sensation of tension across the eyes.

The protrusion of the eyeballs becomes so excessive that they are almost immobile. Enormously chemotic conjunctivas bulge out like shining red projections between the eyeballs and eyelids. Vision may become impaired as the result either of changes in the optic nerve or of the lagophthalmic keratitis, which attacks the unprotected cornea. In favorable cases in which the proptosis stops spontaneously or is checked by operation the corneal infiltrations heal, leaving leukomas, but usually they change into necrosis with perforating ulcerations and panophthalmia necessitating bilateral exenteration of the eyeballs. After removal of the eyeball the swollen orbital contents may prolapse for months through the palpebral slit, but then they undergo a gradual diminution. Malignant exophthalmos is comparatively rare. The literature contains reports of about eighty cases. Compared with the enormous number of strumectomies the rareness of malignant exophthalmos suggests that special conditions not directly concerned with the operation or the decrease of thyroid hormone make the appearance of the protrusion possible. Hyperthyroidism and proptosis may be coordinated, mutually independent phenomena. The question arises whether their common cause might be a secretory disturbance in the anterior lobe of the pituitary. This theory is supported in two different ways: (1) The adenohypophysis has a regulating influence on the function of the thyroid and (2) certain hypophysial disorders, such as Cushing's disease and acromegaly, may be attended by protrusion of the eyeballs. Experimental research suggests that malignant exophthalmos might be caused by hyperactivity of the anterior lobe of the hypophysis concurrent with a postoperative reduction in the function of the thyroid. In the beginning, corneal desiccation may be prevented by tarsorrhaphy, conjunctival plastics or bandaging with petrolatum and gutta-percha paper, but it will soon become necessary to try canthotomy and relaxing incisions in the chemotic conjunctiva and along the base of the eyelids, eventually combined with removal of orbital fat. Roentgenization of the orbit seems to be without effect. Since proptosis necessitated bilateral exenteration in many cases of malignant exophthalmos, more extensive operations have been taken into consideration. Dollinger's procedure of cutting a wedge-shaped piece of bone out of the lateral orbital wall, although successful in excessive ophthalmic goiter, has as yet not been tried in malignant exophthalmos. Naffziger suggested intracranial decompression of orbit and optic canal. With Naffziger's technic access is obtained transfrontally by two flaps of bone to the anterior cranial fossa, where the orbital roof and the upper wall of the optic canal are resected, after which the orbital fascia is opened and a relaxing incision is made in the annulus zinnii. Naffziger later extended the operation by removing also the temporal and a little of the posterior wall of the orbit. Immediately after the operation the protrusion is seen to decrease, the eyes become more mobile, the corneal ulcerations heal and the visual acuity improves. A third method suggested by Sewall and successfully applied by Kistner is the radical removal both of the frontal sinus and of the ethmoid cells. Sewall's operation supposedly is easier than Naffziger's and the resulting cicatrices are smaller. Naffziger's or Sewall's operation should be carried out as soon as the first signs of incipient optic neuritis or of corneal ulceration are observed.

- *Essential Juvenile Anemia Due to Iron Deficiency (Chlorosis). G. Alsted.—p. 1338.
- Two Cases of Cushing's Syndrome in Men. E. W. Flensburg.—p. 1342.

Essential Juvenile Anemia Due to Iron Deficiency (Chlorosis).—Alsted describes the six cases observed in the medical department of the Frederiksberg Hospital during the last ten years. The age distribution is somewhat higher than that reported in earlier cases and menstrual disturbances seem less frequent. There were indications that the diet had been quantitatively and qualitatively deficient. The patients responded well to massive iron therapy, a rise of 1,000,000 erythrocytes occurring within a week. The author proposes the term "essential juvenile iron deficiency anemia" instead of chlorosis.

Opportunities in the Practice of Medicine

WILBURT C. DAVISON, M.D.

DURHAM, N. C.

Medicine probably is the only field today in which a well educated graduate is sure of making a living and also of having security if he carries disability, life and old age insurance. Except for crowding in the larger cities, there is no unemployment problem for American medical graduates. Although he will not make a fortune, as large medical incomes may be a thing of the past, the average physician's income at present probably is at its highest level. According to national figures, 30 per cent of the three and one half billion annual total cost of medical care is for physicians, or \$3,800 net per physician. However, this net figure is based on many physicians who are not in practice, and the correct average net income probably is higher. "Average incomes" may be misleading. A few very large incomes do not help the physician who is not earning enough to enable him to maintain the standards of good practice. However, physicians with extremely high and low incomes are in the minority; no physician's income can be compared with those of the leading lawyers, but physicians have not found it necessary to seek other fields to eke out an existence, as is the case with some lawyers.

One of the reasons for this difference in the status of physicians and lawyers is that the ratio of the former to the population has been declining during the past century from 1:569 (including all healers) in 1850 to 1:742 in 1940.¹ Though medical students have increased during the last twenty-five years from 14,891 to 21,302 in spite of the reduction of the medical schools from ninety-six to seventy-seven, the population has expanded faster than the medical graduates.¹ Raising the educational standards of

modern physicians, the improved quality of present medical service and the increased recognition by the public of the need for better medical care also are factors in the present status of the medical profession.

The standard of a physician's living depends on his medical training, professional and business ability, energy, personality, common sense, location, hospital and other affiliations and his specialty, including general practice as a specialty. The first six of these factors are obvious, but the last three need discussion.

LOCATION

Other areas also may need medical service, but in the South the ratio of physicians to the population is 69 per cent lower than in the North (table 1). That this dearth is not primarily due to the reduction of American physicians but rather to their maldistribution is indicated by the fact that during the last thirty years the concentration of medical men in the Northern urban states decreased only 3 per cent, from a ratio of 1:609 in 1906 to 1:629 in 1936, which is still too high, while in the South the reduction was 21 per cent to 1:1,063. In some Southern counties the ratio of physicians to population is as low as 1:4,500,² although 1:1,000 is considered necessary, especially in rural communities.³ Conclusions that the medical profession is overcrowded and that the condition can be relieved by reducing the number of students entering our medical schools,⁴ though correct for New York, Boston, Philadelphia and Chicago, are invalid for the South or any other predominantly rural area. Over half of the 241 counties in the United States with inadequate medical service are in the ten Southern states.⁵ The distribution of medical services, physicians, hospitals and nurses is more impor-

tant than their actual number. There is more hazard to the public and to the medical profession from scarcity of physicians in certain areas than from overcrowding in others.⁶

This uneven distribution is even worse if it is remembered that the average age of physicians

TABLE 1.—Population per Physician in 1936

(Total U. S. A.)	118,724,606	165,163	719

in rural counties is 52 years.⁷ In Tennessee, for example, only 43 per cent of the physicians in the cities are over 50 years of age, in contrast to 77 per cent of those in the rural areas.⁸

Another disturbing condition in the rural areas is the paucity of recent graduates; 51 per cent of the young graduates located in places under 5,000 population in 1906, but only 11 per cent of the graduates of 1915 and merely 9 per cent of the class of 1920,⁹ although 48 per cent of the population live in communities under 5,000.

FACTORS RESPONSIBLE FOR SCARCITY OF PHYSICIANS IN RURAL AREAS

The three factors apparently responsible for the scarcity of physicians in the South or in any other rural area are the financial return, scattered population and living conditions.

Financial Return.—A survey⁹ of three rural counties in Tennessee, Georgia and Mississippi in 1931 demonstrated that the money spent for medical care was inadequate to remunerate practitioners or to support hospitals and other medical facilities. Three reasons tend to be responsible for this low economic status: (1) The

per capita spendable money is low, (2) a year of unfavorable weather or a lowered market for cotton, the chief "money" crop, creates a depression and (3) the Negro population decreases the economic average and increases the need for medical care. However, voluntary hospital care associations will greatly improve the situation. For example, the annual hospital bills in these three counties varied from nothing to \$319, but if spread over the population the annual cost would have been 98 cents per capita. If hospital bills can be met, the people usually can and do pay their professional charges. A recent survey of the capacity of the various states to absorb more physicians, based on their need for and ability to support medical service (table 2), ranked the ten Southern states eighteenth to thirty-ninth.

At present, owing to the improvement in farming conditions but more especially to the dearth of physicians and to the absence of competition, the incomes of the keener rural doctors often are equal to those of their urban brethren, and even better if the cost of living is considered. In some areas, subsidy by the community has been attempted, although this policy generally has been unsatisfactory.¹⁰ In recent years, the number of rural physicians increased 8 per cent without subsidies.

Scattered Population.—Although the density of the population is increasing in the Southern states, the rate has not been as rapid as in the North (table 3). Obviously the maintenance of a practice and of a hospital is more difficult in an area with fifty-three people per square mile than in one with 286. Furthermore, the distribution of physicians in the Southern states naturally follows the density of the population. The area per physician in North Carolina in 1927 ranged from 3.6 square miles in an urban

county to 203.8 square miles in a rural area, with an average of 21.7 square miles per physician.² Improved roads, however, have greatly reduced the time consumed in making visits.

Living Conditions.—Rural life is all right if one likes it, but only those of us who were

ditions. However, the social factor of unfamiliar surroundings, as well as the uncertainty of financial returns, probably deters the surplus city physicians from migrating into the country.⁶ Not only are “city raised” physicians unhappy if they locate in the country but their patients often do not like them. A few “city raised” physicians have settled from time to time in one rural county with one physician to 4,000 of the population but moved away within a year as they could not establish practices, although the “country raised” physicians in that area have more than they can do and welcomed additional practitioners.

The South will not get its physicians by migration; the students should be Southern, and to get country doctors it must be possible for students from the rural counties to study medicine. “We are oblivious to social facts in trying to devise some plan to get our graduates to go to the country. That is impossible with city graduates. Our real problem is to devise a plan whereby we can get students to come from the country. They are the ones from whom the rural practitioner must be recruited. The country lawyer, the country preacher, the country banker and business man, as the country doctor, do not go from the cities; they come from the country. And unless we succeed in devising some exotic substitute which the country will accept, we shall have to devise some plan whereby the country doctor can be developed from the country boy.”⁷ Graduates tend to return to the environment to which they are accustomed. For example, 83 per cent of the country students at the University of Tennessee returned to rural practice, and 80 per cent of the urban youths later practiced in the city. In Tennessee a campaign of publicity from 1925

to 1930 called attention to the need for country doctors. The ratio of students from rural counties at the University of Tennessee College of Medicine responded at once, and by 1927 the number of graduates going into country practice began to increase.⁶ No accurate figures are obtainable on the percentage of rural students in other medical schools compared to the ratio thirty years ago, but apparently it is much lower.

Rural students, owing to the poverty of farmers, rarely are wealthy or have resources for raising money. Probably the best way by which a sufficient number of country students can attend medical school is through loan funds, which can be repaid over a period of years and thus become available for future students. Scholarships, such as those of the Commonwealth Fund, for students who agree to practice in the country, are splendid and have demonstrated their success but require too great an outlay to be widely available and usually do not create in graduates a healthy sense of obligation toward their community and university. A revolving loan fund on which 6 per cent interest is charged is an ideal investment for university endowment funds, as medical students can and do repay their debts, and it will enable keen rural students to return to country practice. Medical schools should trust their product; if they have no confidence in them, who will? Duke students after their first year may borrow up to \$450 a year at 6 per cent,

* These hospitals have 50 per cent of the total bed capacity of the United States, although they represent only 10 per cent of the total number of hospitals.

and the principal is repaid in instalments starting two years after graduation. An average of \$10,000 lent annually has enabled practically every Duke medical student to continue his education. A state which needs physicians could obtain them, not only without cost, but actually at a profit by establishing similar loan funds. Cheaper medical education is not a solution.

HOSPITAL FACILITIES

The distribution of physicians and that of hospitals are mutually dependent. Physicians rarely will practice and remain in a community without hospitals, and a hospital without adequate medical personnel is not a hospital but a somewhat dangerous hotel. The young, highly trained physician of today does not feel that he can practice modern medicine without access to a hospital. Even though 90 per cent of patients can be and are properly cared for in their homes or in the physician's office,¹¹ the laboratory facilities of a hospital are essential for the diagnosis of many conditions. The establishment and maintenance of rural hospitals in North and South Carolina with the aid of the Duke Endowment not only is improving the medical service in the country but also is attracting young graduates there. In addition, local hospitals influence the older physicians who have kept abreast of the times to remain in rural communities. One of the major objectives of the Duke Endowment is to bring about a better distribution of well trained physicians by an improvement and an extension of available facilities for the practice of modern medicine which exist in and not apart from hospitals.¹²

A complete medical service is a tripod of which the three legs are (1) hospital facilities, (2) nurses and technicians and (3) physicians,¹³ the last being the basic element. Modern medicine often is unsatisfactory without modern facilities not only for the seriously sick who are brought to the hospital but also for the less seriously ill who are to be found in their homes throughout the country. The influence of the location of hospitals on the distribution of physicians is strikingly illustrated in North Carolina; in the fifty-seven counties which have hospitals there is one physician to every 1,149 people, and in the forty-three counties without hospitals the ratio is 1 to 2,034.¹⁴ Of the 638 ten year graduates who have settled in North Carolina since 1925, only sixty-four located in towns without hospitals.¹⁵

The phenomenal growth of hospitals in the United States has been reflected in the South, but the Southern hospitals still have a much smaller average number of beds, and the population per hospital bed is thrice that of the urban North (table 4).

Not only do rural communities need hospitals, but equally important, if they have a hospital, they require financial assistance to enable the people to use the hospital. Bed occupancy is as

vital as the beds themselves. Modern medical service cannot exist without hospitals, and hospitals cannot survive without support from endowments, state, county or federal aid, or voluntary hospital care associations. Because of present financial conditions, endowments are becoming rare, and state, county and federal aid may bring political control.¹⁶ The voluntary group hospital care association seems to be the logical answer. England started the movement, and Texas and North Carolina demonstrated its practicability in the South. Church gifts to hospitals help, but the hospital contributions of the 2¾ million members of one denomination have averaged less than 1.5 cents per member annually, while the Hospital Care Association in Durham, N. C., paid the hospitals an average of \$7.13 per member annually.

SPECIALTY

The answer to the question "Is the general practitioner doomed?" is "No," and that to the query "Is the profession overspecialized?" is "Yes." It is true that only 25 per cent of the recent graduates intend to do general practice,⁸ that the number of general practitioners has been steadily growing less, and that the average age of those left is increasing. However, as a well trained general practitioner can and does successfully treat over 80 per cent of disease, and as his volume enables him to treat his patients at a lower cost, the public needs and wants more general practitioners. The fact that 75 per cent of the present graduates are or plan to be specialists who are needed by less than 20 per cent of the patients is an indication not only of the overcrowding of the specialties but also of the urgent need and wide open opportunities for good general practitioners. This plethora of specialists has caused such competition and crowding that in many Southern communities the financial rewards of general practitioners, with their reduced competition, are higher than those of specialists. The modern medical curriculum often is blamed for this trend toward specialization, but the tide toward general practice is turning without any changes in the medical schools; it is a response to economic conditions.¹⁷ Since the law of supply and demand is causing a larger percentage of the present graduates to enter general practice, it behooves medical schools to study this field so that students may be better prepared for it.

An analysis of the diseases treated by Tulane graduates indicates that a general practitioner's visits consist of obstetrics and gynecology 10 per cent, minor surgery 15 per cent, and the remaining 75 per cent divided among sixty-eight common conditions. Ninety per cent of

17. Davison, W. C.: Duke University School of Medicine, Tr. M. Soc., N. C. 74:35-39, 1927.

general practice is done outside the hospital, approximately 55 per cent in the office and 35 per cent in the home. About 75 per cent of office visits are for minor surgery, respiratory infections, general medical disorders and venereal diseases, and 90 per cent of home visits are for respiratory, general medical and contagious diseases, obstetrics and minor surgery.¹⁸

A generation ago general practitioners spent most of their time treating children. Now, with the ratio of children to the total population reduced during the past twenty years from 1:3 to 1:4, with diphtheria, whooping cough, dysentery and typhoid becoming rarities, with pneumonia and meningitis successfully treated with sulfapyridine or other drugs, with congenital syphilis reduced through the expansion of the program for treating pregnant women, with infant feeding simplified, and with the mortality in children decreased 66 per cent, most of a general practitioner's present patients are adults.¹⁹ However, the need for preventive pediatrics cannot be overemphasized; 75 per cent of the deaths among children are preventable. The distribution of a general practitioner's income also has changed. Formerly approximately 50 per cent came from obstetrics, in contrast to 30 per cent of his time,²⁰ 25 per cent from pediatrics, in contrast to 50 per cent of his time, and 25 from adult medicine, in contrast to 20 per cent of his time. A recent analysis reported 20 per cent of a general practitioner's income from obstetrics, 30 per cent from pediatrics and 50 per cent from adult medicine.²¹ The percentages of time spent in each group were similar to those of the income.

One difficulty in persuading young graduates to go into general practice is their erroneous feeling that it does not carry the same dignity as that of a specialty. Since the specialty boards were created, the students have increasingly obtained the impression that general practice is what the specialists discarded. As a matter of fact, general practice is just as much a specialty as pediatrics, and the present misunderstanding would be corrected if general practice had its own specialty board and requirements. The general practitioner needs a sound scientific background as much as if not more than a specialist, so that he may be capable under all circumstances of advising the family whether the patient needs to consult a specialist.²² A rural physician needs a more prolonged training than a city practitioner, for he must be better able to meet his problems unaided.

All graduates, and especially those desiring to enter general practice, should spend at least two years in hospital work. This is required of Duke graduates, and 80 per cent of them have spent more than this minimum. These internships preferably should be "straight" services rather than "rotating," which often provide merely a smattering of several subjects. If a graduate plans to enter general practice—a consummation much to be desired—a straight medical internship for one year, a straight pediatric internship for six months and a straight obstetric internship for six months would equip him much better than the usual rotating service. Duke Hospital has made this training possible by adding to its "straight" internships in other fields a combined obstetric-pediatric internship of one year. Three months

* The students of the two year schools are not included, as some of them subsequently are graduated from other Southern schools, although many go to Northern schools.
† University of North Carolina and Wake Forest College also have two year schools, and the latter is starting a four year curriculum in 1941.

of this time is spent in hospital obstetrics and gynecology at Duke under Dr. Bayard Carter, three months on the Outside Obstetrics Service, Charlotte, N. C., under Dr. W. Z. Bradford, five months in hospital pediatrics at Duke and one month on infectious diseases at the Sydenham Hospital, Baltimore, under Dr. M. G. Tull. It is hoped that all state boards of licensure will recognize straight internships in any field rather than only rotating services.

SUMMARY

Even though certain factors have decreased the demand for medical personnel, e. g. the reduction of preventable diseases and the increase in telephones, hospitals and nursing, the South, in order to have adequate medical service, needs nearly twice the present number of physicians (table 1) and a threefold increase in hospital beds (table 4), especially in the rural areas. The problem is to find the former, build the latter and support both of them. The twelve Southern four year schools graduated 763 physicians in 1936 (from thirty-three to

113 per school; table 5). If all of them settled in the South, and they do not, they barely would replace the losses by death among the 22,807 physicians in the ten Southern states.

The solution is threefold: improving Southern medical schools, expanding Southern hospitals and making possible the education of Southern country youths. The first is being done rapidly

by the cooperative efforts of the universities and the foundations, the second can be accomplished by voluntary hospital care associations, and the third requires the establishment of loan funds for students from rural areas so that more Southern students can obtain a medical education and become Southern rural general practitioners.

Studying Tropical Medicine in Puerto Rico

MANUEL BERGNES '41 AND JOSHUA WEINER '41

LONG ISLAND COLLEGE OF MEDICINE

BROOKLYN

Last February a notice appeared on the bulletin board at Long Island College of Medicine about an opportunity for third year students to study tropical medicine in Puerto Rico. We applied and learned of the teaching project instituted by Dr. Thomas J. Le Blanc, professor of preventive medicine at the University of Cincinnati College of Medicine, and Dr. George W. Bachman, director of the School of Tropical Medicine in San Juan, Puerto Rico. Under this plan, small groups of students had, in two previous years, spent part of the summer between the third and fourth years in San Juan engaged in brief but intensive study of tropical medicine in its natural setting. Staff members of the school and of the insular health department and various hospitals and clinics in San Juan and elsewhere cooperated in the teaching program.

We sailed, June 13, on the *S. S. Coamo*. The passengers were mostly university and preparatory students returning to their homes in Puerto Rico for the summer. We were impressed with their charm, vivacity and torrents of musical language, which were too much for our Spanish. We made many acquaintances among Puerto Rican students of dentistry, parasitology, bacteriology and medicine.

The School of Tropical Medicine is one of the outstanding architectural achievements in San Juan, patterned after the Palacio de Monterey in Salamanca, Spain. The school program consisted of one week each of study in entomology, pathology, mycology and public health and two weeks of clinical work. The first week was spent under the guidance of Dr. William Hoffman, medical zoologist, who had been in Puerto Rico fourteen years. We studied the taxonomy of mosquitoes and observed in the laboratory the eggs, larvae and adults of various species of *Anopheles*, *Culex* and *Aedes*. Then we went into the field, visiting heavily infested areas and collecting larvae and adult forms. We had the experience, quite discouraging for the novice, of dissecting mosquitoes under the microscope looking for filariae.

In the parasitology laboratory was an amazing collection of material for the study of para-

sites prevalent in Puerto Rico and elsewhere. The laboratory studies were supplemented by excursions to the haunts of the insect vectors, in the course of which we absorbed information concerning the local flora, fauna and mores.

The last day in the department of medical zoology was devoted to field work on a larger scale. We observed poorly protected cesspools and other breeding places for mosquitoes in the vicinity of human habitations and found the larvae of *Anopheles* in abundance. We searched for the molluscan host of *Schistosoma mansoni*, the fresh water snail *Australorbis glabratus*, which thrives in the contaminated waters of certain streams. As we collected snails, small boys wading in the streams were seen to have splenomegaly and ascites characteristic of schistosomiasis. This was a forceful demonstration of the presence of this disease in these river valleys.

The week end was spent traveling across the island visiting hospitals, clinics and other places. We left San Juan and drove along the old Spanish road, the Carretera Militar, through Rio Piedras, Caguas, Cayey, Aibonito, Coamo and Juana Diaz, reaching Ponce on the Caribbean coast. In Ponce we visited La Clinica Pila, Tricoche City Hospital and St. Luke's Hospital, where much clinical material was demonstrated to us. From St. Luke's, which is on a hill, could be seen the entire city and in the distance the aptly named island Caja de Muerto, which rests on the Caribbean Sea like a giant coffin. The next stop was the Ryder Memorial Hospital in Humacao, where some unusual cases of tropical disease were demonstrated.

At Santiago Island we visited what is said to be the world's only free range primate colony. Afterward we drove through the Caribbean National Forest, up to the crest of El Yunque, where the vegetation was of rare variety and interest.

The second week at the School of Tropical Medicine was devoted to the pathology of tropical disease and the special problems connected with the practice of medicine in the tropics.

Under the teaching of Dr. Enrique Koppisch, these studies were carried out in a large room in the tower, which commanded a view of the harbor, the airport, the mountains, the city and the ocean. This week was given to malaria and blackwater fever, schistosomiasis, chromoblastomycosis, the filarial diseases, elephantiasis, leprosy, madura foot and mossy foot, sprue, balantidiasis, yellow fever, yaws, ainhum and hydatid disease. The reading of necropsy protocols and references to the literature supplemented microscopic studies of diseased tissue. Dr. Koppisch presented the material with such clarity that this week proved to be the backbone of our studies in Puerto Rico.

In the study of hematology Dr. Rodriguez-Molina emphasized the anemia of sprue, which is common in Puerto Rico. The secondary anemias associated with uncinariasis, the blood changes in malaria and in schistosomiasis, and the high incidence of eosinophilia in Puerto Rico were discussed. Almost a week was spent in studying mycology. The climate of Puerto Rico is conducive to the growth of fungi. Lectures were supplemented by the study of cultures and by clinical contacts with the diseases discussed.

A week with the Department of Health impressed us with the work being carried on under the dynamic Commissioner of Health, Dr.

Garrido Morales. We saw the subsoil drainage program of malaria control, from the making of the cement pipes to their installation with subsequent conversion of malarial swamp-land into cane fields. Hookworm is being controlled by the distribution of latrines manufactured by mass production methods. Tuberculosis, a serious problem in Puerto Rico, is vigorously attacked. We visited the sanatorium at Rio Piedras, the clinics devoted to the pneumothorax treatment of ambulatory patients, venereal clinics, bacteriologic laboratories, pediatric clinics, health centers in the smaller towns, the mental hospital and the leper colony, where there were fifty-four lepers.

The clinical work consisted of ward rounds at the University Hospital of the School of Tropical Medicine, the Presbyterian Hospital and the Bayamon District Hospital, the latter the first of a number of projected 300 bed well equipped district hospitals. The ward rounds brought us to realize that, although tropical diseases may present themselves as single diagnostic entities, they more often appear in conjunction with other diseases which constitute the problems of general medicine.

We returned to El Yunque for a farewell party with those who had so hospitably received us. On August 5 we were back in New York.

Digests and Reviews

MEDICAL EDUCATION

Abstract of remarks by A. Lawrence Lowell, President of Harvard University, Boston, published in the New England Journal of Medicine, March 21, 1940.

Education in medicine is more difficult than that in any other profession because it involves the knowledge of many subjects which, apart from their relation to medicine, have no natural connection. In a medical curriculum, gross anatomy has to the beginner no obvious connection with biologic chemistry, bacteriology or pharmacology. Each involves a brute effort of memory and is largely forgotten before the time comes for its application to the practice of medicine or surgery. Whether there is an advantage in learning more facts than can be retained depends on the nature of the facts and their effect on the mind. When fresh illustrations of a thought produce familiarity with the idea and thus render it more easily reproduced, it is well. This is true of making a diagnosis or watching an operation but it is not true of striving to memorize more facts than the mind can retain; and medical knowledge has far passed that point today. Therefore the selection of basic topics ought to replace the attempt at omniscience.

There is a disadvantage in the length of medical education, and that is the late age at which

the physician is able to begin active practice. He gets through medical school and hospital not earlier than 26—far older than a man ought to be when he begins his work in life, and in most cases too near the end of the age of greatest intellectual fertility.

At the other end of his career, if he has an appointment in a hospital he loses it, as a rule, at 62; and very commonly his private practice therewith. Perhaps the age of retirement is too early or too late—too early if it means withdrawing from the community the benefit of his experience, too late if it means turning over to his juniors the bulk of the work at the hospital while retaining some supervision and a sufficient teaching clinic.

As things stand, the man with a permanent hospital appointment—out of a useful life which could last, let us say, on the average until 70—has a maximum of some thirty-six years for conducting a practice to which he has devoted, including the two premedical years, a minimum of eight years to professional training. That seems disproportionate; what is more, the length of training has been increasing and the age of hospital retirement becoming lower.

In the last half century the age of entering Harvard, and no doubt other colleges, has been reduced almost exactly one year: from 19 and

three months to 18 and three months. I should like to see it fall six months more, for I think reasonably intelligent young men are capable of excellent intellectual development at that period of life. I should much regret to have the students of our best medical schools lose the benefit of contact with other young men in a college of liberal arts, the more so because I lament the withdrawal, as compared with former times, of the physicians from civic affairs, to which they could contribute much.

One who has had a chance to see the medical school only from the faculty table may get impressions of value because he is detached from the interest of teachers in their fields. One sees that interest in the planning of the present Harvard Medical School with four separate establishments for the four chief laboratory subjects, each capable of containing an entire class, with its big lecture room unused three fourths of the time. The impression is that those who planned the school intended to exclude from anatomy and from physiology, for example, any infiltration of the other as something alien to its nature. The old conception was the attainment of medical knowledge by study of many separate fields; that of the present is correlating those fields into one great subject of medicine as a coherent whole.

Formerly the laboratory and clinical professors sat on opposite sides of the faculty table, and if an additional appointment was made to one group it was expected by the other also, that the balance might be maintained. Such an attitude is inconceivable today. The clinic makes constant use of a laboratory, and the laboratory teacher appreciates more fully that his aim is to fit men for practice.

The interest of the medical teacher in his own field as something distinct from medicine as a whole has been greatly reduced, partly at the Harvard Medical School by the general examination for graduation, which has caused both student and teacher to correlate laboratory and clinical knowledge in a striking way. It is strange that this highly effective device has been little copied in other medical schools, for people still regard examinations mainly as a test of work done, whereas their most important function is setting a standard of accomplishments.

For a nonprofessional observer to tell experts how to improve their methods would be presumptuous, but he may properly observe that the results are in some respects defective from the standpoint of the community and of the profession.

Vast improvements in medical education have been made in the last half century but there seems to have been a tendency to add the new to the old without eliminating some things no longer needed.

THE GENERAL PRACTITIONER AND MODERN MEDICINE

Abstract of an article by Dr. J. P. Simonds, professor of pathology, Northwestern University Medical School, published in the June 1940 issue of the Marquette Medical Review.

Medicine has always been interested in everything that can influence the well-being of mankind. The modern physician, especially the general practitioner, must be something of a botanist to understand an ailment so common as hay fever; something of a zoologist to appreciate the relation of parasites and disease; a physicist to comprehend the electrocardiograph, the action and defects of x-rays and radium; a chemist to grasp the underlying conditions of diabetes and exophthalmic goiter; an anatomist to know where to look for an inflamed appendix; a physiologist to distinguish between the normal activities of the body and its disordered functioning in disease; a cytologist to understand cancer; a pharmacologist to know how drugs may influence disease. He must be something of a herpetologist if he practices where poisonous snakes are abundant; a bacteriologist if he is to understand infectious diseases; a diplomat who can say just enough to be within the truth, but neither too little nor too much to do harm in an inquisitive patient; a psychologist in order to understand the whims of his patients; a moralist with high ideals of personal conduct; a humanitarian who loves his fellow men, and a good Samaritan to the suffering.

CRITERIA FOR SUCCESS IN GENERAL PRACTICE

Only the most brilliant men in medicine should go into general practice. Even low grade mediocrity often succeeds in a specialty; only the most intelligent, alert and active minds can attain real success in general practice. This is not a field into which graduates in medicine should drift just because they have not the intelligence, the ambition or the energy to enter a specialty; it should be undertaken as a matter of definite choice with a full knowledge of its requirements, its possibilities, its demands.

But the specialist has an important place in the practice of medicine. When the general practitioner has, after a complete study of a patient, arrived at a correct diagnosis, he may not have the opportunity or the time to develop the skill necessary to do a delicate and extensive operation. Then he calls in a surgeon. But he should be able to tell the surgeon all about the patient and his condition and he should know as well as or better than the surgeon what should be done for the patient. The general practitioner cannot in such instances complete his work for his patient unless he does call in a specialist. He is like the architect, who, with his wide knowledge of stone and steel, plumbing

and electric wiring, heating and ventilation, cannot bring into being the magnificent building unless he has the help of the man with the steam shovel to make the incision in the earth for the foundation and the structural steel worker to put in place the beams which bind the whole together.

THE GENERAL PRACTITIONER

Modern medicine is appalling in magnitude. Discoveries of new methods, new remedies, new active principles are made rapidly. The specialist has only an advancing margin of medical progress to keep up with, but the general practitioner must cover the entire field. By what criteria can the general practitioner determine what is of value among the unrelated tidbits of new medical knowledge published in countless contributions in medical journals? The "reviews" that form an important part of the medical literature today are not always helpful. Often they are mere catalogues of results of observations and experiments, without any attempt to assign them their position in the framework of modern medicine. For acceptance of what he reads the general practitioner will have to depend on his common sense, his intuition, a sense of fitness and his knowledge of correlative facts.

Medical knowledge exists in strata. Some has been deposited for a long time and is fully consolidated and therefore a sure foundation for practice. Other strata are in process of being laid down and are often disturbed by the ebb and flow of the tides of new discoveries. One must learn to recognize medical truth in both its filmy costume of the abstract as well as in the homely dress of the practical. Truth is discovered in a variety of ways.

Modern medicine is highly mechanized. Both patient and doctor lose much as a result of this change. Many teachers today, especially in the clinical branches, are poor examples to students of what a general practitioner should be. They have lost the self dependence and self confidence that characterized doctors of former generations. Today the physician who is the model of medical students sends his patient to the hospital, where some one in the laboratory makes an x-ray film and reports his observations, the cardiologist interprets the electrocardiogram, the pathologist diagnoses the sections of a tumor removed, a technician determines the nonprotein nitrogen of the blood and does a blood count and a urinalysis. After these experts have given the doctor the benefit of their experience in making a diagnosis, why should he do any thinking in the case? Why should he listen with utmost care to the chest and percuss the borders of the heart? The roentgenologist will tell him whether the heart is enlarged and if so whether it is a mitral or an aortic type of enlargement

or whether it is due to a cardiac aneurysm following coronary thrombosis. The roentgenologist will tell him whether there is tuberculosis, a tumor or pneumonia in the lung or fluid in the chest cavity. The intern or the resident takes the blood pressure; the nurse takes the temperature. The older doctors, using their own thoroughly trained five senses, determined most or all of these physical signs of disease themselves about as accurately as it is done today with the modern mechanical devices. And, unfortunately for both patient and doctor, the patient has to pay for all of this laboratory and x-ray work and, no matter how reasonable the doctor's fee, the patient and his family frequently feel that they have been unjustly treated.

The general practitioner, if alert, will learn how to do without many of the mechanical adjuncts of medicine. He will gain in self confidence and in self respect, he will win the respect and confidence of his patients as well as their gratitude because of his fair treatment of them financially, and he can be just as good a doctor as his more highly mechanized teachers.

OPPORTUNITY TO SAVE MEDICINE FROM SOCIALIZATION

We hear much of socialized medicine. The practice of medicine, because of its intimately personal nature, cannot be successfully regimented. Of all our citizens, the general practitioner can do more to save our threatened system of free enterprise than any other single group. When general practitioners tell their patients what the loss of our system of free enterprise will mean to them and to every one in this country, what meddling with the practice of medicine by bureaucrats will mean to the health of their children and their community, how socialization or state control of medical practice might well be a prelude to the complete destruction of free enterprise, they know that what he says is true. The general practitioner occupies not merely a strategic position in this changing world but he can, more than most groups, control the direction and extent of the change that must come with changing conditions. His quiet comments and advice, his reputation for justice and fair dealing, his common sense will do more to prevent the disasters that would follow the regimentation of medicine under the state or under any alien social order than any other one social force.

General practice is the very foundation of the science and art of medicine in this country. The work of the general practitioner is the criterion by which may be judged the quality of the medical service of any community. He is the strongest line of defense against the

invasion of medical practice by those who are untrained and unqualified either to render or to control such services. He will be a strong force in maintaining our system of free enterprise. In paraphrasing the words of Goldsmith:

*Ill fares the land, to disease and death a prey,
Where bureaucrats accumulate and doctors decay.*

FUNCTIONS OF THE PRECLINICAL SCIENCES

Abstract of an article by Dr. Magnus Ingstrup Gregeresen, professor of physiology, Columbia University College of Physicians and Surgeons, and published in Science, March 29, 1940.

The general purpose of a medical school is to train physicians. This training is constantly undergoing changes resulting from advances in science. The student must realize at the start, therefore, that he must obtain a foundation which will not crumble under these advances. He must develop a capacity to alter his concepts according to new facts and establish the habit of assimilating facts in a way that will increase his confidence even as he finds some of his earlier training misconceived. Much of what he will learn rests on insecure experimental evidence. Other phases of his work will be well founded. He must learn to distinguish between the two. This he can do only by drawing his own conclusions from what he regards as well established facts. Such a scientific attitude is the student's most valuable weapon.

A large part of the medical course is devoted to studies in which the student has no contact with patients. These studies are designed to give an understanding of the structure and function of the body. For this purpose medical schools support large faculties and expensive laboratories.

The emphasis on research in preclinical departments is criticized by those who do not fully understand the relation of these sciences to experimental medicine and to the intent of faculties of medicine in training students. The spirit of research has a vitalizing effect on the teaching staff. By stressing this experimental attitude in teaching students the preclinical sciences fulfil their most important function in medical education.

The part of the laboratory is to train the student to make his own observations, in order that these may form the groundwork on which he builds his knowledge. In many instances the technics he employs are also to be his tools

in clinical studies, and it is important that he examine them critically. Above all, the purpose is to establish confidence in his power to observe and to reason correctly from his observations. This can be accomplished only by practicing the experimental method.

A phase of teaching about which there is a difference of opinion is the writing of theses based on the reading of original articles. Scientific literature is vast. Practice in finding one's way in it, learning to get the gist of articles without great waste of time, is a necessary part of medical training. Students who depend solely on textbooks miss the flavor of scientific inquiry. The medical curriculum makes heavy demands on students. How to keep them from becoming confused and swamped is a problem that falls mainly to the lot of the preclinical departments, which they meet in their first year.

I cannot overemphasize the necessity of correlating facts from the very start of your course. Don't expect to see or be shown at once the relation of each detail to the practice of medicine. You cannot start at both ends at once. Begin with the small circle of facts under immediate observation and let the extent of your attempts to correlate grow with your acquisition of knowledge. Gradually will come general principles which will serve to simplify the learning process.

Stimulation of the student's will to learn is the chief purpose in pointing out the practical application of certain facts to medical problems. One must not devote too much time to this approach in the preclinical courses, for it may focus the student's attention on specific facts that happen to be of immediate practical value rather than on knowledge of the science as a whole. Failure to observe the difference between fact and its interpretation has caused many needless controversies. You will find that there are contradictions in the opinions and interpretations of instructors in different departments. These need not be a source of confusion, provided we agree on the facts. Some professors impress their opinions on students with such authority that these opinions are regarded as unalterable facts. We must guard against this tendency, for nothing is more destructive to the freedom of thought and creative thinking, the very qualities we aim to encourage. The student must never feel that he will be penalized for expressing an honest well founded contrary opinion in our midst.

DO YOU KNOW WHAT PHYSICIAN—

1. Wrote "The Chambered Nautilus"?
2. Was a candidate for the nomination for President of the United States in 1920?

3. Designed the United States Capitol in Washington, D. C.?

The answers are on page 2238

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items for consideration for publication in the Student Section.

Columbia Students Assisted

In the annual report for the year ending June 30, 1940, the dean of Columbia University College of Physicians and Surgeons, New York, states that during the year 115 students received scholarships and grants totaling more than \$40,000. The average award was \$354. Many of the students obtain employment during vacations, and even a larger number work throughout the school year in order to continue their studies. More than 50 per cent of the entire student body has been assisted by scholarships, loans and employment. It is to be hoped, the dean says, that more financial aid can be obtained for the students who have a class, hospital and clinic schedule which makes remunerative employment difficult, to say the least, and who face long internships and hospital training which make substantial borrowing undesirable. Scholarship aid is by all criteria the most satisfactory manner of helping many deserving young men and women ambitious to render public service through some phase of medical practice, science, teaching or health work.

Johns Hopkins Medical History Club Celebrates

The famous librarian Dr. John S. Billings in 1889 brought from the Surgeon General's Library in Washington, D. C., to a meeting in Baltimore several rare medical publications and manuscripts, an incident which stimulated interest in medical history and led to the establishment by Drs. William Osler and William Welch of the Johns Hopkins Medical History Club, which celebrated its fiftieth anniversary November 18. Osler was unflinching in his attendance at the meetings of this club, and it was on these occasions that such well known essays as "The Alabama Student," "Thomas Dover," "John Keats, the Apothecary Poet" were presented before the students and others in attendance.

Jobs for College Students

More than 150,000 young people are being enabled to continue their education in the nation's colleges and universities during the present academic year through jobs provided under the college and graduate work program of the National Youth Administration of the Federal Security agency, it has been announced. Colleges and universities have been assigned employment and fund quotas on the basis of 9.47 per cent of the total number of resident undergraduate and graduate day students from 16 to 24 years of age, enrolled as of Nov. 1, 1939, and carrying at least three fourths of a normal schedule. For the academic year 1940-1941, the national student quota is 101,846. Figures compiled as of April 1940 show that the National Youth Administration paid an average monthly wage of \$13.46 to college and graduate students participating in the program. The average wage of the undergraduate was \$13.25 a month, while that of the graduate student was \$21.78. Undergraduate college students are permitted to earn an amount, established by local authorities, between a minimum of \$10 a month and a maximum of \$20, while graduate students may earn from a minimum of \$10 to a maximum of \$30.

The total allotment of college and graduate work funds for the academic year 1940-1941 amounts to \$13,713,225. The allotments to the states are made on a monthly basis, usually over a nine month period;

however, in some instances the institutions operate on an eight month basis and are allotted funds accordingly.

Young people between the ages of 16 and 24, inclusive, who need assistance in order to continue their education are eligible for employment on the NYA college and graduate work program, which operates in nonprofit-making, tax-exempt, bona fide educational institutions. Officials of each institution have the responsibility for selecting the students and for supervising their work, which includes research and laboratory work, building and repair of equipment, construction and repair of buildings and other school facilities, clerical and stenographic work and library assistance. A total of 1,712 institutions participate in the college and graduate work program.

Hospital Residents Present Programs

Residents of St. Louis hospitals were invited to present the program before the St. Louis Medical Society, November 12. Participating from Barnes Hospital were Drs. William R. Arrowsmith and Samuel P. Harbison, speaking on "Reasons for the Failure of Iron Therapy in Certain Cases" and "Crystalline Sulfanilamide and Wound Healing" respectively; from City Hospital, Dr. Leo V. Mulligan, "Major Amputations in Gangrene of the Lower Extremities," and from Firmin Desloge Hospital, Drs. Henry E. Oppenheimer and Joshua E. Jensen, "Observations on the Effect of Vitamin K" and "Thrombocytopenic Purpura—Relieved by Splenectomy—Report of a Case" respectively.

West Virginia Seminars

At the regular seminar at West Virginia University School of Medicine, Morgantown, November 12, the student body was addressed by Dr. William L. Mullins, assistant professor of medicine, University of Pittsburgh School of Medicine, on heart disease; in the seminar October 25, by Dr. Edward G. McGavran, county health officer, on functions of county health departments as they relate to the practice of medicine, and at that on October 11, by Dr. George R. Maxwell, Morgantown, on the heart in the practice of medicine.

Harvard Class Plans Gift to School

The class of 1925 of Harvard Medical School, Boston, at its reunion in New York in June enthusiastically approved the proposal that the class raise \$10,000 to be given to the medical school at the class reunion to be held in 1950, the money to be invested by the university and the income to be used for the medical school.

Applicants for Admission to Columbia

The dean of Columbia University College of Physicians and Surgeons, New York, Dr. Willard C. Rappleye, in his annual report for the year ending June 30, 1940, states that 413 students were enrolled in the regular course for the degree of doctor of medicine during the year, of whom 103 were seniors and 107 freshmen. There were 1,048 applicants for admission to the first year class. The students had prepared in 163 different colleges and universities. The class admitted during the year had prepared in forty-seven colleges. The graduating class obtained internships

in fifty-three different hospitals in all sections of the country. One hundred and ten students who were registered under the graduate faculties of the university took their work at the medical school during the year. Instruction in the medical sciences for the school of dental and oral surgery was provided for the students of that school. There were 194 residents in the hospitals affiliated with the graduate medical program, of whom fifty-two were registered for the degree of doctor of medical science. In the post-graduate courses offered at thirteen hospitals, 1,061 physicians were registered from forty-three states and twenty-three foreign countries.

Dr. Gates Addressed California Seniors

Senior students at the University of California Medical School, San Francisco, the faculty and guests were addressed in November by R. Ruggles Gates, Ph.D., LL.D., professor of botany, King's College, University of London, London, England, on "The Biology of Human Blood Groups." Dr. Gates in 1915 lectured at the Genetics Congress in San Francisco and in that year published his book, "The Mutation Factor in Evolution"; in 1916 and 1917 he was acting professor of zoology at the University of California. In 1929 he published a reference book on heredity in man and became deeply interested in human blood groups, which during his extensive travels he investigated in various native peoples in South America, India and Canada.

Tufts Scientific Forum

The Scientific Forum at Tufts College Medical School, Boston, is an organization that gives students an opportunity to present papers. The following students presented papers before this group during recent weeks: Alfred G. Chandler '42 on "Diagnosis of Brain Tumors"; Robert W. Riemer '42, "Nervous Indigestion"; Jerome C. Saltz '42, "Specific Treatment of Chronic Arthritis," and Dudley B. Tyson '42, "Psychoneuroses as Seen in General Practice." The president of the Scientific Forum this year is Robert W. Riemer.

Field Day at Wisconsin

To promote fellowship and better understanding between the teachers and students at the University of Wisconsin Medical School, Madison, is the object of the annual field day which is held in the spring. The day begins with a review of research being carried on by students. There are special exhibits, a luncheon, then an address by some well known guest. The respective classes give vent to their rivalries in base ball games in the afternoon and finish the day at a banquet which both faculty and students attend.

Music Room for Harvard Students

A music room has been fitted out in the students' dormitory, Vanderbilt Hall, at Harvard Medical School, Boston, for the comfort and entertainment of students, and the library has been redecorated with new lights and new chairs. The dining room rates have been changed, so that more students may be able to take their meals there.

California Lecture

The senior students and faculty of the University of California Medical School, San Francisco, were recently addressed by Wendell L. Stanley, Ph.D., of the Rockefeller Institute for Medical Research, N. Y., on the subject of viruses. Dr. Stanley during this semester is Hitchcock Lecturer at the University of California.

Duke Premedical Student Wins Scholarship

Joseph W. Taylor Jr., Tampa, Fla., a premedical student at Duke University School of Medicine, Durham, N. C., has been awarded a tuition scholarship at Duke as one of five members of his class having the highest averages. According to the *Tampa Tribune*, Mr. Taylor is also a member of Phi Beta Kappa and of other honorary clubs and a member of the Duke University golf team.

Tennessee's Comprehensive Examinations

When a student at the University of Tennessee College of Medicine, Memphis, completes the first six quarters of the medical course, the privilege of registration in the seventh quarter is withheld for one quarter until the student is given a comprehensive examination on the preclinical courses by a committee appointed from the clinical staff. The object is to determine the student's fitness to undertake the clinical courses. The examinations, which require three nights to complete, are individual and oral. The winter comprehensive examinations at the University of Tennessee College of Medicine will be held Jan. 2-4, 1941.

"DO YOU KNOW WHAT PHYSICIAN"

Following are answers to the questions appearing on page 2236:

1. Oliver Wendell Holmes, who for thirty-five years was professor of anatomy and physiology at Harvard. In 1843, while still a medical practitioner in Boston, Holmes reported his discovery of the contagiousness of puerperal infection. These observations were confirmed several years later by a young Hungarian physician, Ignaz P. Semmelweis.

2. General Leonard Wood, who graduated from Harvard Medical School in 1884 and for many years served in the medical corps of the U. S. Army. Later he was transferred to the line and became chief of staff of the army and governor general of the Philippine Islands. General Wood died in Boston in 1927.

3. Dr. William Thornton. In October 1792, Dr. Thornton requested from the commissioners an opportunity to present a plan; his request was granted and his plan accepted by the commissioners April 5, 1793. Some fourteen plans for a capitol building had been submitted by others previously, but none was wholly satisfactory. In the development of Dr. Thornton's plans in the erection of the first unit of the Capitol Building, three architects were employed—Stephen H. Hallett, George Hadfield and James Hoban, the architect of the White House. The erection of the south section of the Capitol, which is now occupied by Statuary Hall, was under the charge of B. H. Latrobe. The dome of the original central building, constructed of wood covered with copper, was replaced in 1856 by the present structure of cast iron, completed in 1865. The dome receives light through 108 windows. Dr. Thornton was born in 1761 on the Island of Tortola, West Indies, and received his M.D. degree in Edinburgh in 1784. He continued medical study in Paris and then came to Washington, D. C. He served as the commissioner of the District of Columbia for eight years. President Jefferson appointed him clerk of patents, and later he became the first commissioner of patents. Dr. Thornton became a member of the Medical Society of the District of Columbia in 1819, the year in which the society received its first charter from Congress, and was vice president of the society 1820-1823. He died, March 28, 1828 and was buried in the Congressional Cemetery.

ROENTGEN THERAPY FOR BRONCHIOGENIC CARCINOMA

EUGENE T. LEDDY, M.D.

AND

HERMAN J. MOERSCH, M.D.

ROCHESTER, MINN.

In this review we propose to compare the results obtained from roentgen therapy in a group of 125 cases of proved primary bronchiogenic carcinoma with another group of 125 proved cases in which neither roentgen therapy nor any other form of therapy was employed. Considered here, a proved case will be regarded as one in which tissue from the tumor on microscopic examination has shown the presence of carcinoma.

In all cases in our study there was microscopic confirmation of the clinical diagnosis. This point is important, because we know from experience that to make a differential diagnosis between primary carcinoma of the bronchus and other types of pulmonary lesions is often difficult. Although roentgenologic examination of the thorax is of the utmost importance in the diagnosis of this condition, it is well known that considerable inaccuracy exists in precise differentiation between primary carcinoma and other lesions by this method.

All of the 250 patients to be considered in this study were examined by the same group of clinicians and roentgenologists, and the treatment was given by the same group of radiologists. Of course, many more patients than 125 have received roentgen therapy for primary carcinoma of the bronchus, but since there were only 125 patients who did not receive any roentgen therapy it was thought advisable in our study for purposes of comparison to limit the group who did receive such therapy to the same number as those who did not.

We were first desirous of determining whether or not there was any criterion which guided the clinician in his decision as to which patient should receive roentgen therapy and which should not. In general, the untreated patients were in more precarious physical condition than those for whom roentgen therapy was advised. However, it must be said that in the earlier days of our experience with primary carcinoma of the bronchus it was generally thought that roentgen therapy was of practically no value for this condition; consequently patients were dismissed once a positive diag-

nosis had been established, regardless of their actual physical condition.

All authorities agree that primary carcinoma of the bronchus occurs more frequently in men than in women. In our group, for every woman affected there were four men (table 1). Healthy adults in the prime of life are most often afflicted (table 2). Extremes of age may also be encountered in rare instances; one of our patients was 2½ years of age and another 80 years of age.

Many hypotheses have been advanced to account for the apparent increase in incidence of bronchiogenic carcinoma. The roles of infection, irritation and heredity all have been advocated and denied by most observers. The patients in our group were predominantly farmers, but we could not elicit any tangible etiologic factor.

Primary carcinoma of the bronchus is usually insidious in its onset, and it is often difficult to distinguish it from other forms of pulmonary disease. It may therefore be overlooked, owing to the fact that the symptoms at the onset may blend imperceptibly with the clinical symptoms that may exist as a result of other pulmonary disease. In certain instances, however, there is a history that the patient apparently enjoyed perfect health and then suffered a sudden onset of symptoms such as pulmonary hemorrhage or severe paroxysms of cough. As may be readily seen by a review of table 3, most of our patients had symptoms that dated back for several months before the patients came for examination. Nine patients gave a history of symptoms that covered a period of two years or more before a correct diagnosis was established.

From the standpoint of symptomatology there was no difference whatever so far as the clinical course was concerned between the two groups in our series (table 4). It is important to emphasize that at times primary carcinoma of the bronchus may remain silent and the presenting symptoms may be those caused by metastatic focus. It is also important to point out that negative results on roentgenologic examination of the thorax do not always rule out the possibility of an underlying carcinoma. A physical finding that should always cause one to suspect the possibility of the existence of a bronchiogenic carcinoma is the absence or diminution of breath sounds over any portion of the lung. In a number of our cases this physical finding alone led to bronchoscopic examination, with subsequent establishment of the correct diagnosis.

The sites of metastatic foci in our cases as shown by clinical or roentgenologic examination are given in table 5. It should be mentioned in this connection

From the Section on Therapeutic Radiology (Dr. Leddy) and the Division of Medicine (Dr. Moersch), the Mayo Clinic.
Read before the Section on Radiology at the Ninety-First Annual Session of the American Medical Association, New York, June 12, 1940.

that the incidence of these signs is at variance with that given in other reports because the incidence herein given occurred among living patients.

The sites of occurrence of the bronchiogenic tumors in our cases are given in table 6. It is noteworthy that there was a rather low incidence of peripheral

tumors, such as those originating near the pleura, and those of the "Pancoast" type. This may be attributable in part to the fact that in the majority of the cases in our study the diagnosis was based on microscopic examination of tissue obtained through the bronchoscope. Thus, many cases in which the lesion was situated in the periphery of the lung and in which the diagnosis was not established until necropsy were not included in this study.

Table 7 illustrates the histologic classification of the tumors in our study. To avoid all controversy over classification we have divided them according to their obvious structure, that is, adenomatous or epitheliomatous, and have subdivided them according to their index of malignancy as determined by Broders personally. Such a classification is simple, clear, not ambiguous, and easy to use; it seems to us more advantageous than other more elaborate and perhaps more confusing classifications.

Outstanding in table 7 is the high incidence of tumors of the highest grades of malignancy. In fact, of the 250 tumors that we are considering, 212 were

of the most malignant type. There is, however, nothing remarkably different in regard to the distribution of tumors according to their index of malignancy whether in the treated or the untreated groups. As a matter of fact, the index of malignancy played no role whatever in deciding whether a given tumor was or was not suitable for roentgen therapy.

For the purpose of record it can be stated that there was one case of hemangio-endothelioma of the trachea.

One of the eight cases of adenocarcinoma grade 1 occurred in the trachea, one in the left upper lobe and two each in the right main bronchus, the right middle lobe and the right lower lobe, respectively. As is well known, these tumors are the so-called adenomas of the bronchi about which there has been much controversy.

Considering the types of patients that we have treated with roentgen rays, it is unfair to compare the value of operative procedures with the value of roentgen therapy in cases of bronchiogenic carcinoma. Even though the indications for pneumonectomy are not always followed rigidly, the radical operation is generally reserved for patients who have a relatively small localized tumor and who present no evidence of distant metastasis or of marked physical deterioration. The indications for roentgen therapy, on the other hand, are in general that the patient is not suitable for radical operation or that he refuses it. In short, operation is generally attempted in only carefully selected cases.

In the evaluation of surgical results in a carefully selected group of suitable cases, one must not forget

the immediate mortality of the operation, which is still high even in the hands of the most skilled operators. To be fair, however, one must admit that progress is being made in this field and that, theoretically, radical operation still offers the patient his best chance of a cure if he survives the operation. But the patient with a bronchiogenic carcinoma is in difficult straits to decide whether to assume the high surgical risk, with a chance of curing his condition, or to take roentgen therapy, with a chance of prolonging life for an indefinite period.

On the other hand, if one abandons the idea of cure as the criterion by which the value of any therapeutic method is to be judged one can allocate to roentgen therapy a place among the valuable palliative procedures, comparable perhaps to the surgical treatment of gastric or renal cancer or to the medical treatment of cardiac, hepatic and other well known degenerative diseases. Considered thus, it seems more sensible to judge the results of roentgen therapy for bronchiogenic carcinoma from the point of view of its benefit to the patient after due consideration of the expense and the wear and tear, if not the actual misery, undergone by the patient during his treatment.

In an attempt to evaluate roentgen therapy for bronchiogenic carcinoma we will present an analysis of the results which we have obtained in a group of

125 proved cases of bronchiogenic carcinoma in which treatment has been given by various roentgenologic methods (tables 8 and 9). The terms which we have employed to designate the various kinds of treatment in the tables are sufficiently well known by most radiologists to obviate further elaboration of them. However, we should like to call attention to a point of view long held by many radiologists besides ourselves, namely that less than three courses of treatment with the "massive" technic are insufficient for all but the exceptional case. Judged in this light we think that 102 of our 125 patients had entirely insufficient roentgen therapy.

There are several reasons for this state of affairs. First, many of these patients were treated in the early days when the value of roentgen therapy was regarded as hardly greater than that of any other experimental procedure. Second, the physical condition of many patients was not good enough to justify anything more than a mild, or at most a single, course of treatment. Third, the results of the first course of treatment were

than a year after proof of his diagnosis. Such a situation shows the fallacy of a statistical analysis for "cures" and seems to indicate a fertile field in which earlier diagnosis may improve the final results.

An analysis of the results of roentgen therapy shows some interesting and, at times, paradoxical results. It

often too discouraging or too indefinite to warrant continuation of roentgen therapy. Fourth, the inconvenience of further treatment at the clinic owing to personal circumstances of the patient made complete treatment impossible. Fifth, there are no exact indications to be followed in either planning or administering roentgen therapy. Sixth, knowledge of the advantages of repeated courses of treatment, based on experience, was slowly acquired.

One of the important reasons why the results of roentgen therapy are not better is the poor general condition of the patients which precludes adequate treatment. That statement is proved by the high death rate that occurs within six months or less in both the treated and the untreated groups. Not only were ninety-nine patients in the terminal stages of the disease, but also of those who did receive some treatment little was accomplished because thirty-seven of them died within four months.

Three patients lived a year or more without treatment after histologic proof of the diagnosis. As a matter of fact, all three of these patients had roentgen therapy elsewhere, but we have listed them as untreated because they did not receive treatment at the clinic. At any rate, we do not know of a single patient who is known not to have had any roentgen therapy who lived more

does not seem that the results of technically superior treatment were consistently better. The discrepancy can be explained easily by the fact which we have mentioned before, that we are not considering all the patients who had roentgen therapy.

Twelve patients had incomplete or "placebo" treatment, and two others had roentgen therapy of moderate voltage. Rather than send these patients home untreated and in a hopeless condition, this kind of treatment was given. Not one of these patients survived for six months. All fourteen patients, who for all practical purposes were untreated, followed the course of the untreated patients.

It should be noted that the data which we are considering do not permit any conclusions regarding the merits of any technic of treatment, because not all patients who had roentgen therapy are considered herein. It so happens that most of the patients in this review were treated by the so-called massive dose technic. However, a few patients treated by the "Coutard method" are also included. We think, therefore, that the question of the best method of

treatment had better remain unanswered for the present.

We have already given our reasons for not considering fourteen cases in the group when forming a judgment of the results of roentgen therapy for bronchiogenic carcinoma. If, now, we deduct those additional patients who, according to accepted criteria, were insufficiently treated (since they all received less

than three courses of treatment) there remain twenty-three patients who may be regarded as completely or sufficiently treated. The remaining eighty-eight patients had various degrees of incomplete treatment.

Regardless of the amount of roentgen therapy which they actually received, twenty-five of these 125 patients

that these results were produced by methods of treatment that have no associated mortality and also that all of the 125 treated patients were beyond hope of benefit from operation. Since no patient who was not treated with roentgen rays survived for longer than a year, and since twenty-five patients who were treated lived from one to twelve years, the absolute value of roentgen therapy as a palliative measure for bronchiogenic carcinoma seems self evident.

TABLE 9.—*Technic of Roentgen Therapy*

lived for at least one year after treatment. Table 10 shows the data concerning these patients. It seems to indicate that, in general, adenocarcinoma grade 1 has the most favorable prognosis of all these lesions and that, as a whole, patients with adenocarcinoma do better than those with epithelioma. Fifteen of these twenty-five patients had adenocarcinoma. Of these

fifteen lesions four were grade 1, two were grade 2, four were grade 3 and five were grade 4. Ten of these twenty-five patients had squamous cell epithelioma. Of these ten lesions, five were grade 3 and five were grade 4.

In evaluating our results of roentgen therapy in cases of bronchiogenic carcinoma, one should keep in mind

SUMMARY

In this series of 250 cases of proved bronchiogenic carcinoma the prognosis was poor because of the advanced stage of the disease at which a correct diagnosis was made. Nevertheless our results show not only that roentgen therapy is an excellent method of palliation but also that it has produced so-called cures. We therefore think that any patient who is not in too precarious a physical condition deserves to have at least one course of roentgen therapy; otherwise his life expectancy is, at most, one year. On the other hand, twenty-five patients in our series have lived from one to twelve years after roentgen therapy. The data are inconclusive but it seems that, in general, adenocarcinoma is a more favorable type of tumor than epithelioma. The question of the best method of treating bronchiogenic carcinoma with roentgen rays had better remain unanswered for the present.

ABSTRACT OF DISCUSSION

DR. MAURICE LENZ, New York: It is generally admitted that roentgen therapy of bronchiogenic carcinoma may relieve cough, expectoration, hemoptysis and pain in the chest. It is doubtful whether this treatment prolongs life. As it is difficult to fix the date of onset of the disease, a claim of increased survival following roentgen therapy must be based on a comparison of a sufficient number of treated and untreated patients. This has been done in a thorough and unbiased analysis of 125 treated and 125 untreated patients with cancer of the lung by Drs. Leddy and Moersch. While the results are encouraging, they naturally do not compare with the results in microscopically similar tumors in more accessible locations. The authors have emphasized the fact that patients referred for roentgen therapy of bronchiogenic carcinoma usually have extensive local disease. Vigorous irradiation is not practical in such cases because of concomitant injury to large volumes of normal lung tissue which have to be included. Added to this difficulty is the danger of increased breaking down if an abscess cavity is associated with the cancer, especially if it is situated, as is frequently the case, in an atelectatic lobe. The dosage administered in bronchiogenic carcinoma is therefore much less than that proved adequate in similar carcinomas in more accessible locations. If cases were referred earlier so that only small fields would be needed to include the entire disease, larger doses could be administered and perhaps would offer more hope. I believe that the entire dose should be administered in the first and only course of treatment before retrogressive changes in the normal tissues, due to preceding irradiation, preclude the administration of adequate x-ray dosage. On the basis of autopsy and clinical records of 121 untreated and sixty-eight treated cancers of the lung, Dr. William Tenzel, my associate at Montefiore Hospital, concluded that there was a direct relationship between the length of survival and the x-ray dose estimated to reach the tumor. Thus the length of survival was raised from eleven and a half months to twenty-two months when the "estimated tumor dose" was increased from 2,000 roentgens to about 6,000. It is only by such carefully substantiated studies as set forth by Drs. Leddy and Moersch that we may hope to convince the clinician of the importance of sending earlier cases of carcinoma of the lung for roentgen therapy, and this offers the only hope for improvement in therapeutic results.

IMPROVED TECHNIC FOR REMOVAL
OF SEMILUNAR CARTILAGE AND
POSTOPERATIVE TREATMENT

HAROLD R. BOHLMAN, M.D.

Instructor in Orthopedic Surgery, Johns Hopkins
University School of Medicine
BALTIMORE

Fifteen years ago I was impressed with difficulties attendant on internal derangements of the knee. Principles of diagnosis were not as clearly defined as at present. Operation often resulted in many weeks or several months of disability and too often produced a joint lacking full free motion. Convalescence was frequently long and painful and the entire procedure costly. In 1927 I¹ began aspirating joints and injecting air before and after operation as a matter of routine. This experience indicated hemorrhage as probably the greatest disturbing factor. Much blood in the joint before or after operation may result in irritation, infiltration, swelling and thickening of the synovial membrane and ballooning of the joint capsule. Formation of fibrin and its absorption or organization often results in adhesions within the joint. This train of events prolongs immobility. Hence a study was undertaken with a view to keeping free blood out of the joint cavity after operation.

Arthrotomy of a normal joint can be done with a minimum of trauma, with complete hemostasis, permitting early function, a minimum period of convalescence and early return to normal activity.

PREPARATION

Problems of diagnosis will not be considered except to note that, whenever increased fluid or hydrops is present, aspiration followed by injection of air to produce moderate tension within the joint is carried out. Adequate x-ray examinations are made from whatever angle may be indicated.

The state of the joint from the standpoint of arthritis is noted. A general investigation is next carried out. Possible focal infections are searched for. Occasionally I insist that an abscessed tooth be removed or prophylaxis of the mouth performed, a sinus irrigated or a pair of tonsils removed, or a chronically infected prostate or cervix first treated.

Next a careful history is taken of wound healing, whether or not ordinary scratches or cuts heal by first intention or are prone to fester. In the latter event a patient is checked with Burky's² toxin for sensitivity to staphylococcus toxins and, if necessary, a course of intradermal injections of Burky's toxin is given to raise immunity.

Careful blood studies are next carried out with special reference to the cell and platelet counts, bleeding time, clotting time, clot retraction time and the prothrombin time. If there is deviation from normal in any of these, a thorough study is carried out to determine its nature, cause and correction, particularly if there is disturbance in the clotting mechanism.

Allergy to iodine, procaine hydrochloride, narcotics or the ordinary drugs which might be used is investigated.

The knee, thigh and calf are invariably scrubbed with green soap and gauze, bristle brushes being avoided; the extremity is then shaved and the area cleaned with alcohol, ether and third-strength iodine (preferably the night before operation) and swathed in sterile towels, which are removed before operation, when the skin is coated with full-strength iodine unless the patient is sensitive to it. In these rather rare cases the gentian violet solution which I introduced³ is used.

ANESTHESIA

Local anesthesia is preferred; 3 grains (0.2 Gm.) of pentobarbital sodium is administered by mouth to adults a half hour before operation. One per cent procaine hydrochloride is used; from 20 to 40 cc. is injected into the joint after aspiration. The line of incision is next infiltrated, not more than one drop of epinephrine per ounce of solution being employed to prolong the anesthesia; a greater quantity will cause postoperative hemorrhage. Spinal anesthesia is occasionally used and rarely a general anesthesia. The more explosive types are avoided, as is the closed ether method. This precaution is necessary when the electrocautery is used.

OPERATION

The affected extremity is draped free and so arranged that it can be flexed to right angles over the side or the end of the table.

A tourniquet is never used. I agree with Aleman and Friberg⁴ that it is apt to cause thrombosis in the older patients; it increases the postoperative pain, swelling and local disturbance. A tourniquet prevents hemostasis and permits postoperative intra-articular hemorrhage. Voyer⁵ cautions against it for these reasons and believes that it lowers natural resistance to infection.

A short longitudinal or slightly oblique parapatellar incision is preferred but this is varied, depending on the size and structure of the knee and the associated internal derangement. In this regard, Basset's⁶ book is instructive. I avoid curved or cross incisions and injury to the medial or lateral ligament and, if possible, the patella or patellar ligament. However, in elderly persons with marked osteo-arthritis the entire patella has been removed as advocated by Mader.⁷

All bleeding points are carefully clamped or coagulated by the suction tip with the high frequency electrocautery.³ The joint is thoroughly inspected. The anterior end of the meniscus is freed with the acusector, the suction tip being held near to remove smoke and clear the view. Any bleeding points are carefully coagulated as this proceeds. The cartilage is then cut along its base, the vascular area being avoided. At first an insulated curved acusector was used but was found to be unsatisfactory. More recently the knife designed by Lowe and Breck⁸ has greatly facilitated this procedure. I have had no experience with the

Mercer⁹ knife or with the use of the Leggiadro¹⁰ knife. The entire posterior portion is removed as advised by many authors, if necessary, through posterior incision. Damage to articular surfaces is carefully avoided, as is excessive manipulation of the joint. All enlarged or disturbed portions of the subpatellar fat pad are removed. The joint is thoroughly inspected for loose bodies, synovial villi, adhesions or other pathologic disturbances as suggested by MacAusland.¹¹ It is then thoroughly lavaged with the procaine solution, minus epinephrine, or physiologic solution of sodium chloride, the suction being used to prevent wetting of dressings. This is a simple apparatus, 9 inches long, made of number 30 stainless steel tubing, carrying a hose connection threaded on the proximal end, with a 4½ inch insulated handle. The distal end is slightly curved over the outer 2 inches, the tip being rounded, carrying a pin-sized central opening with four similar sized openings about the circumference of the tip. A small stilet of stainless steel wire, which can be passed through the central opening, is kept at hand to clean the small holes. There is a grooved metal collar at the upper end of the insulated handle which permits contact of the electrocautery point by the assistant. This simple instrument, properly handled, greatly reduces the operative time and loss of blood, keeping the field clear. Ordinary bleeding points touched with it are momentarily dried and the current coagulates them without charring; this reduces the amount of foreign material in the wound, promotes healing and greatly reduces the possibility of infection. In the deeper regions it is most convenient; quickly applied to bleeding points, it produces hemostasis with little trouble.

A blended spark gap and tube current is preferred.³ A good head lamp greatly facilitates the whole procedure.

Lavage with physiologic solution of sodium chloride washes up any loose bits of tissue, indicates any bleeding points, clears the wound of air-borne bacteria and prevents drying of the raw tissue surfaces.

Fingers are kept out of the wound as much as possible but, if necessary, exploration is carried out with a finger after washing the gloved hands with mercury bichloride solution. The joint is immediately afterward lavaged with physiologic solution of sodium chloride. Sponges are kept out of the wound. They are apt to leave lint within the joint, which forms minute foreign bodies. MacAusland¹¹ cautions against sponges.

The joint is then filled with physiologic solution of sodium chloride, which may be diluted with procaine hydrochloride; the synovium is carefully matted with fine black silk sutures, as are the remaining layers of tissue. The skin is closed with lock stitches of the same material. Alcohol soaked gauze is placed over the wound and covered by wrappings of sterile glazed cotton. The entire leg and posterior portion of the foot are encased in a light plaster splint or crinoline and strips of basswood, with this dressing moderately snug about the knee. Some of the joints have been closed and air injected before the dressings were applied; this or the fluid, with moderate pressure of the outer dressings, reduces the possibility of chance hemorrhage from any of the coagulated points.

CONVALESCENCE

When local anesthesia is used, sweating, shock and loss of fluid associated with general anesthesia is avoided, likewise the break in food intake, all of which shortens convalescence and greatly reduces postoperative complications. The patient is permitted to sit up in bed the same day and is allowed up in a wheel chair on the third day with the affected leg horizontal. Many patients are permitted crutches on the fifth day. The splint is removed on the sixth or seventh day; also the stitches. The joint is then aspirated of any fluid and its character noted. From 20 to 40 cc., or a sufficient amount, of air is then injected to produce moderate pressure. Both passive and active motions are started. Increments of activity with regard to amplitude of motion and weight bearing are gradually and steadily increased. Patients who do not have complications bear almost their full weight on the twelfth day and use a cane on the fifteenth day. Many have been returned to full activity with no disability three weeks from the day of operation, with no synovial thickening or disturbance other than slight tenderness about the operative scar.

Injection of air is of great help in convalescence. If hemorrhage has occurred, a sufficiently large bore needle to remove it is employed. The joint may be lavaged with physiologic solution of sodium chloride through this needle until the fluid returns quite clear, when air is injected to act as a cushion. Fluid is not compressible while the air cushion prevents adhesions, adds to comfort¹ and permits greater and earlier mobility. Occasionally it is necessary to aspirate and inject a second time. MacAusland¹¹ nine years ago remarked on the stiffness of a joint resulting from hemorrhage. A number of patients treated in the manner described on postoperative aspirations have shown no abnormal amount or character of synovial fluid and invariably progressed to an early and complete recovery with no disability. Some of them have been carpenters, one of whom returned to full occupation on the eighteenth day after operation. Patients who do not have complications receive no physical therapy.

COMMENT

In this group of fifty cases no infection of a joint occurred. Two elderly women developed superficial stitch abscesses in the subcutaneous fatty tissues; since then stay sutures of silkworm gut have been employed instead. Twenty-six were uncomplicated cases with a hospital stay ranging from a minimum of three days to a maximum of seven. Total disability of eighteen days in one case ranged to three or four weeks; in others, up to a maximum of six weeks, females invariably progressing more slowly than males. Five females did not have complications. The maximum postoperative temperature in this group was 100.8 F. and was of short duration.

Three of the fifty cases were misdiagnosed and at operation found to be simple osteochondritis dissecans, one chondromalacia patellae and one a congenital malformation with a band of tissue snapping across the upper portion of the external condyle. One proved to be multiple chondromas, another osteochondromas with alcaptonuria. Still another was complicated by a cyst of the external cartilage and five with osteoarthritis; one by a loose body. There were five cases associated with fracture of the head of the tibia or of the condyles. Ages ranged from 8 to 61 years. Those

cases complicated by fracture or arthritis were much slower to recover and required physical therapy.

Three were complicated by hemorrhages due to blood dyscrasias, one of which responded immediately to vitamin K therapy. One peculiar case with a history of purpura and previous hemarthroses, with a very peculiar blood picture, did not respond to the administration of vitamin K, food changes or other vitamin therapy, except that the general appearance improved. The first case in which there was extensive postoperative hemorrhage occurred early in the series; there was profuse bleeding at operation and the knee joint filled with blood after operation and on aspiration a week later again refilled. Convalescence was slow, requiring three or four months, but the patient eventually obtained a knee with normal range of fairly smooth motion. In one case acute appendicitis developed the second day after operation and one was complicated by carcinoma of the uterus. One knee was opened following a second injury which damaged the external meniscus a year after removal of the internal meniscus. This joint was found to be free of adhesions and normal in every respect; there had been some regeneration of fibrous tissue along the base of the internal semilunar cartilage.

Three of the uncomplicated cases were investigated by arthroscopy a year or more following operation and the joints were found to be quite normal. This is in sharp contrast to six knees which have been investigated by exploratory arthrotomy a year or more following operation under tourniquet when the joints were known to have contained a fair amount of blood following operation. Synovial surfaces were found with many adhesions, with diminution of the joint space. Two were found to have tags or apron-like hypertrophied areas of synovial membrane associated with adhesions. These joints all presented varying amounts of limited motion before the second operation, and convalescence following it was prolonged and varying grades of joint disturbance persisted.

Boppe¹² reviewed the procedure of some twenty-one surgeons over the world eight years ago. At that time Porter allowed weight bearing in three days, others in seven, eight and nine, while most permitted weight bearing in from ten to fifteen days with full use by Henderson as early as seven days; but the majority of surgeons preferred about twenty days. A few cases respond well to early movement, weight bearing and activity. Age, weight, the general state of nutrition and the duration and extent of injury are all factors bearing on the rate of progress. Violent early motion may produce hemorrhage in the line of incision or within the joint, complicating recovery.

CONCLUSIONS

I believe that:

1. Local anesthesia is preferable to spinal or general anesthesia.
2. A thorough study of the patient should be carried out before operation.
3. A tourniquet should not be employed.
4. Complete hemostasis should be obtained.
5. Postoperative aspiration followed by injection of air greatly aids recovery.
6. Passive and active motion and function should be established early.

ABSTRACT OF DISCUSSION

DR. ALAN DEFOREST SMITH, New York: Carefulness in preparing patients for operation and attention to details in the operation and postoperative care are to be commended. I have not found it necessary, however, to take many of the elaborate precautions which Dr. Bohlman uses, and I believe that they tend to make the treatment of this condition unnecessarily complicated. I have been hesitant about injecting air into knee joints as a routine procedure, because of the possibility of air emboli. Aspiration of the joint after operation in cases in which there is marked swelling, in order to remove the accumulated blood, is a useful procedure and should be practiced oftener. Hemorrhage after operation is nearly always due to incomplete hemostasis and not to a dyscrasia in the blood clotting mechanism. Operation in every case of internal derangement of the knee, no matter how strongly the symptoms and physical signs may point to a damaged meniscus, is to some degree an exploratory arthrotomy, because there are so many conditions which may complicate or simulate this lesion. I therefore feel that it is necessary to make a generous incision in order that the joint may be explored thoroughly. Dr. Bohlman agrees with the necessity for exploration but nevertheless prefers a short incision. It seems to me that exploration is facilitated by the use of a tourniquet, and I do not believe that this materially increases the likelihood of hemarthrosis after operation, if the tourniquet is removed before the incision is closed and if the bleeding points are ligated. The use of the coagulating current in accomplishing this is certainly helpful. Separate suture of the synovial membrane is in my opinion an important point in securing hemostasis. This has been mentioned by Dr. Bohlman. A number of authors support Dr. Bohlman in his contention that the entire cartilage should be removed. It has not been my practice to attempt removal of the posterior fourth or fifth of the meniscus, which ordinarily cannot be reached without a separate posterior incision, and I am quite certain that this small posterior tab has not resulted in any subsequent difficulty in these cases. Probably no harm is done by applying a splint for a period of a week after operation; I have preferred not to do this but to start motion the day after operation. In spite of what is said about the disadvantages of passive motion, I believe that if this is carried out carefully and gently for a few days until the patient can initiate active movements it helps greatly and practically always adds to his comfort as well as to the early mobility of his joint. I agree with Dr. Bohlman that early weight bearing is possible and desirable. The routine which I have outlined has been used in a large series of cases at the New York Orthopaedic Hospital, and in a follow-up study of 175 cases by Dr. Lantzounis no case of residual stiffness of a joint was found.

DR. PHILIP LEWIN, Chicago: Dr. Bohlman's recommendations were that: 1. Local anesthesia is preferable to spinal or general anesthesia. 2. A thorough study of the patient should be carried out before operation. 3. No tourniquet should be employed. 4. Complete hemostasis should be obtained. 5. Postoperative aspiration and injection of air greatly aids recovery. 6. Passive and active motion and function should be established early. I should like to ask Dr. Bohlman what an acusector is. I want to correct something he quoted from an earlier paper, that Porter was allowing weight bearing in three days. I can assure you that none of his patients were allowed to bear weight in three days. Regardless of whether Porter put in the questionnaire that he was letting them up in three days, or whether it was misquoted, the statement isn't true. I call your attention to a few random notes with regard to atrophy of the quadriceps muscle. There are two muscles in the body that atrophy when anything happens around them, whether disease occurs or especially if they are injured: one is the deltoid, the other the quadriceps extensor. They seem to begin quickly to atrophy. Let me call attention to a certain preoperative position for x-ray examination known as the Bécclère-Holmblad position. One usually says to the x-ray man "We want an A. P. and a lateral." I always insist on three if the patient can be put in the third position. The Bécclère-Holmblad position is one in which the patient kneels on a chair with the knee in a position of about 120 degrees of extension and the central ray is passed through

from behind. If you will do that in every case you won't miss any of these cases of osteochondritis dissecans that were mentioned in the author's paper. About preoperative exercises, I think it is important to tell the patient who is going to have an operation on his knee that he must practice using his quadriceps before the operation. There was a time when I used to give patients a typewritten slip saying "You must practice exercising your quadriceps before the operation because as soon as you wake up from the anesthesia (if it is a general anesthetic) I am going to insist that you raise your heel off the bed regardless of how much or how little pain it causes you." I tell them to tighten the knee, point the toes and raise the heel off the bed. They can do it with only one muscle and that is the quadriceps. If they are used to it before the operation and are thinking about it when going under the anesthetic, it is easy to get them to do it afterward. Postoperatively, they must elevate it whether they have a cast on or not, and if one has a compression cast on, they elevate that straight leg easier than if they have a pressure bandage on.

DR. HAROLD R. BOHLMAN, Baltimore: With regard to Dr. Smith's comment on air embolus, we feel pretty safe in this field. In none of these cases have we had embolism occur, even when we put in air immediately after operating, before we put on the dressings. The human body will tolerate a certain amount of intravenous air. Firor some years ago demonstrated that a dog could tolerate from 18 to 25 cc. of air in his venous system without great difficulty. I have had two cases of air embolism occur in gonorrheal arthritis joints, one of which I tried to distend when adhesions were present and another in which the joint space had been partially obliterated and I used too much tension. The immediate results were startling and very embarrassing to the patient and to the doctor as well, but neither resulted in a fatality. A number of these have been reported in the literature. I once suffered one bit of experience with air emboli in my veins while giving blood for a transfusion and somebody hooked up the vacuum pump in reverse. It was startling to feel the air gurgling up my brachial vessels; it raised my blood pressure and pulse rapidly but did no harm, although it gave me a bad start for a little while. With regard to Dr. Lewin's question on the acuator, that may not be a good term. I have forgotten who used it first, but I use it in association with a small knifelike instrument which has an insulated handle and is hooked up to a machine with a current of radio frequency characteristics. I refer to the Burdick machine, which I believe has a blended spark gap and tube current; for information on this, I refer you to Ward and Kelly's book on electrosurgery, which was published some eight years ago. Quadriceps atrophy I think depends a good deal on the duration of the disability before operation. In the oldest case in this series there were symptoms of twenty-five years' standing. The internal semilunar cartilage was badly chewed up and distributed about the joint, many pieces attached to the synovial membrane, as Timbrel Fisher notes loose bodies often do. This patient had a great deal of atrophy of the quadriceps muscle, but it came back surprisingly fast after a quarter of a century of disability of that knee. It was amazing to see how rapidly, without any particular help on our part, the quadriceps developed form and function.

Vitamin C.—Most animals do not get scurvy, however badly they are fed. They can make their own vitamin C, as the ascorbic factor is called. But monkeys and guinea pigs need it like men. And when Holst and Frölich produced scurvy in guinea pigs in Norway in 1907 it soon appeared that it was due to lack of a substance needed in small amounts; and the quantities in different foods could be roughly measured in doses needed to cure a guinea pig. I was in the next room when Szent-Györgyi, a Hungarian working at Cambridge, isolated vitamin C. He was not looking for it and did not know that his crystals were the vitamin. He had tracked down and purified a substance found in various plants and concerned in oxidations inside the cells of both plants and animals, where it plays a part somewhat like that of hemoglobin in the animal body as a whole.—Haldane, J. B. S.: *Science and Everyday Life*, New York, Macmillan Company, 1940.

COMPENSATORY ATROPHY OF THE ADRENALS

HANS SELYE, M.D.

MONTREAL, CANADA

It is well known that following partial removal of an endocrine gland the remaining parts of the organ tend to compensate for the loss by undergoing active hypertrophy and hyperplasia. This phenomenon has been referred to descriptively as compensatory hypertrophy. The isolation of purified hormone principles made it possible to study the effect of hormone overdosage on endocrine glands, and it soon became evident that in most cases excessive treatment with a certain glandular substance resulted in the eventual atrophy of the cells which normally have the task of producing this glandular product. It is not within the scope of this com-

* In all experiments reported in this paper, the significance of the apparent differences between the treated and control series was evaluated by "Student's" method for small samples (Fisher, R. A.: *Statistical Methods for Research Workers*, ed. 5, London, Oliver & Boyd, 1936, p. 128) and is expressed in terms of probability, estimated by graphic interpolation in Fisher's table of t. In accordance with the usual convention, differences between series cannot be accepted as significant when P is greater than 0.05. In each series the untreated animals or, in case all animals were injected, only the groups receiving oil or cholesterol were used as controls, since treatment with the latter substances proved ineffective in causing a change in the adrenal weight.

munication to review the extensive relevant literature. Suffice it to mention that the thyroid gland undergoes involution under the influence of an overdose of a thyroid preparation,¹ the pancreatic islets, especially the insulin producing beta cells, involute following treatment with insulin,² the ovaries after administration of estrogen³ or progesterone,⁴ the testis after androgen

therapy,⁵ the parathyroids after administration of solution of parathyroid⁶ and the adrenal cortex after administration of adrenal cortex extract⁷ or desoxycorticosterone.⁸ Even the pituitary shows degenerative changes in animals chronically treated with hypophysial extracts.⁹ It appears logical to refer to this atrophy as "compensatory atrophy," since it is the exact antithesis of compensatory hypertrophy and appears to be the result of a readjustment of endogenous hormone production in an organism which is flooded with an exogenously introduced glandular preparation. In the case of the endocrine glands which stand under the regulating influence of the pituitary, it is most probable that compensatory atrophy is due to a decrease in the elaboration of the corresponding tropic hormone. This is shown by the fact that estrogens cause no atrophy in hypophysectomized animals whose ovaries are maintained by daily injections of gonadotropic substance,¹⁰ and cortical preparations fail to cause cortical atrophy in intact rats receiving adrenotropic substance by injection.¹¹

If the phenomenon of compensatory atrophy, as defined, is considered from the point of view of its clinical significance, it is evident that it could never serve to inhibit an excess production of hormone by an endocrine organ since, in order to produce atrophy of an overfunctional gland, one would have to administer a further excess of the same endocrine substance which is already present in unusually large amounts in the circulation of the patient. In such cases the possible benefit which could be derived from the inhibitory action exerted by the hormone on the overactive gland is outweighed by the damage which would be produced by aggravating the existing endocrine overdosage. Yet the endocrine treatment of diseases of hormone oversecretion would appear to be of the greatest clinical significance, since, in spite of all the progress made in the substitution therapy for hormone deficiencies, elimination of the hyperactive gland by surgical means or roentgen therapy are still the only reliable methods of coping with diseases of excess production of hormone.

In view of these considerations, an effort was made to determine whether treatment with glandular substances chemically similar to but physiologically different from those produced by a gland of internal secretion could also result in its compensatory atrophy. It was felt that if this should be the case it might open new methods of therapy, because the direct peripheral effects of the introduced substance would be different from those of the hormone elaborated by the hyperactive gland and would not necessarily aggravate the existing condition of overproduction of hormone.

The discovery that either estrogenic or androgenic substances may cause gonadal atrophy in both sexes,¹² which fact was confirmed with crystalline synthetic androgens and estrogens,⁸ was an encouraging indication that at least in certain cases such a "transferred compensatory atrophy" is possible. However, in this instance the resulting atrophy is most probably due to the inhibition of gonadotropic hormone production, and since the latter is responsible for the maintenance of both ovary and testis it appeared possible that we are dealing with a rather unique example. Yet in cases of excessive estrogen production (e. g. women in the menopause), inhibition of ovarian function by androgens or progesterone (which, as was said, also causes ovarian atrophy) may prove of therapeutic significance. Another observation that may perhaps be interpreted as an example of transferred compensatory atrophy is the observation of de Fremery,¹³ who found that diiodotyrosine causes the normally active thyroid glands of immature rats to assume the resting type. The fact that this inhibition is not due to a direct action on the thyroid is well shown by the fact that the "resting" thyroids of rats treated with diiodotyrosine remain so sensitive to exogenously introduced thyrotropic preparations that the author recommended animals so treated

Fig. 1.—A, low magnification of cross section through adrenal of normal control female rat. B, low magnification of cross section through adrenal of female rat treated with desoxycorticosterone acetate. Note marked involution of the cortex while the medulla is but slightly subnormal in size.

to be used for the bio-assay of thyrotropic extracts. It appears quite possible that the diiodotyrosine molecule, which differs but slightly from that of thyroxine, retains the latter's ability to cause compensatory thyroid atrophy though it loses its other physiologic actions.

In the present communication I report a series of experiments in which the compensatory atrophy of the adrenals was submitted to a systematic study. This appeared especially interesting since the adrenal produces a large number of hormone principles, many of which are available in pure crystalline form. It was thought, therefore, that this gland would furnish an excellent test object on which to study the question of whether overdosage with one hormone principle made by a certain cell could inactivate this cell sufficiently to prevent it from producing not only this but also the other hormones which it usually elaborates.

THE ACTION OF DESOXYCORTICOSTERONE

Among the investigators who studied the action of life-preserving adrenal cortex extracts on the adrenals, some claimed that these produce no significant change¹⁴

plete disappearance of the X zone (figs. 6 and 7A). It appears therefore that this compound, which is not a testis hormone, is capable of causing involution of the presumably androgenic zone. If it should prove correct that the X zone is functionally different from the remaining cortex and is the source of adrenal androgens, one would have to consider this change to be

another example of "transferred compensatory atrophy." In any case the microscopic appearance of the cortical cells was such in all zones of the organ that it seems very probable that their ability to produce hormones other than desoxycorticosterone was likewise impaired, the atrophy appearing to be "transferred" even in this respect.

THE ACTION OF PROGESTERONE

Using relatively small doses (2 mg. a day) of progesterone, I⁸ obtained only slight adrenal atrophy in female rats and none in males. Clausen²⁵ was unable to produce a statistically significant decrease in the adrenal weights in this species, but this might have been due to the fact that he used relatively small doses. In the mouse, Starkey²⁶ asserted, without having experimental evidence to support his assertion, that progesterone might cause involution of the X zone. This has been contradicted by Martin,²⁷ Tolenaar²⁸ and Howard,²² who stated that progesterone in daily doses up to 5 mg. causes no change in the X zone of the adrenal in immature mice. Hence it was concluded that this hormone cannot be made responsible for the physiologic involution of this zone during gestation.

In view of the fact that the experiments mentioned in the previous section showed definitely that desoxycorticosterone causes marked adrenal atrophy, it appeared of special interest to establish whether progesterone, which differs from the latter only in the absence of one -OH group on C atom 21, would have the same effect. For this purpose 12 female albino rats weighing on the average 107 Gm. were divided into two groups of 6. The first group received only 0.4 cc. of peanut oil subcutaneously daily; the second group was injected with 10 mg. of progesterone in the same amount of oil. After twenty days of treatment, all animals were killed. The average adrenal weight in the control group was 40 mg. at this time, while in the progesterone-treated group it was only 29 mg. This decrease is obviously statistically significant since $P = < 0.01$. Another experiment of this type was performed on 12 castrate male albino rats weighing 175 Gm. on the

average. Here again 10 mg. of progesterone was administered daily in 0.4 cc. of peanut oil to one group while the other group was treated merely with peanut oil. The average adrenal weight was 40 mg. in the controls and 36 mg. in the progesterone-treated group. However, this decrease was not statistically significant since $P = 0.3$. The reason progesterone failed to cause more significant atrophy in this group is probably that these animals were much heavier than those of the previous group and yet received the same dose of the substance. Several other experiments in which we studied the action of progesterone confirmed these observations, as they showed that this compound causes some decrease in adrenal weight but is much less potent in this respect than desoxycorticosterone.

In 6 gonadectomized female albino mice having an average body weight of 21 Gm., daily administration of 3 mg. of progesterone caused a decrease in the average adrenal weight from 4.7 to 3.8 mg. ($P = 0.05$), while in 6 males of the same size the average adrenal weight of the noninjected castrates (3.7 mg.) was approximately the same as that of the progesterone-treated animals (3.9 mg.). These results confirm the view expressed in our previously quoted paper, namely that the female organism is more sensitive to this action of progesterone than the male. At the same time a comparison of the atrophy produced in these groups with the decrease in adrenal weight caused by treatment with desoxycorticosterone acetate under exactly identical conditions (see the previous section of this communication) shows beyond doubt that the slight change in the molecular structure of desoxycorticosterone which results in its transformation into progesterone greatly reduces its ability to cause adrenal atrophy.

Microscopic studies of the adrenals of progesterone-treated rats showed lesions which were essentially similar to those elicited by desoxycorticosterone but were much less pronounced. In the gonadectomized

In all other cases the result of combined treatment with two compounds is compared with that of mere estradiol administration.

mouse, the most conspicuous result of progesterone therapy was the disappearance of the X zone in both sexes (fig. 7B).

THE ACTION OF ANDROGENS

While most investigators agree that the X zone of the mouse adrenal disappears under the influence of androgens,²⁹ no significant change in the weight or histologic structure of the adrenal has been observed

in lizards,³⁰ guinea pigs³¹ and dogs.³² Vidgoff and Vehrs³³ stated that in the rat the so-called inhibitory hormone of the testis, which causes involution of the male sex organs, leads to hypertrophy of the adrenal cortex. However, I³⁴ demonstrated that all nonspecific agents which cause gonadal atrophy also produce enlargement of the adrenal cortex, and therefore it appears very probable that the relatively crude testis extracts employed by Vidgoff and Vehrs owe both their adrenal enlarging and sex organ inhibiting actions to their toxicity. Crystalline testosterone causes definite adrenal atrophy in immature females³⁵ and a less pronounced decrease in adrenal weight in adult females,³⁶ but no such decrease could be obtained in adult males.⁸ It is of interest that in the case of early postnatal treatment with testosterone propionate the cortical atrophy is particularly marked in the rat but is due mainly to involution of the glomerulosa.³⁷ In this respect the atrophy differs qualitatively from that produced by hypophysectomy, which, as I mentioned before, is characterized by a predominant reticularis atrophy.

Since the adrenals are smaller in males than in females, the fact that a definite decrease in adrenal weight was obtained only by androgens in female rats might be regarded as an indication that this change is due merely to a "masculinization" of the female. In order to test this possibility my associates and I performed an experiment in a group of 12 newborn albino male rats, 6 of which received 1 mg. of testosterone daily during twenty-four days, beginning on the day of birth. The dose was then raised to 3 mg. daily, the animals being killed on the thirtieth day of treatment. The remaining 6 rats received the same dose of cholesterol during this period and served as controls. The experiment was performed on such immature animals because previous observations taught us that it is easier to inhibit the development of the adrenal than to cause atrophy of a fully developed gland. The average adrenal weight in the controls was 24 mg. as compared with 12 mg. in the testosterone-treated group. The decrease was obviously statistically significant, since even the largest adrenal in the testosterone group was considerably smaller than the smallest of the control glands ($P < 0.01$). This experiment indicates perhaps that one is dealing not merely with a "masculinization" but with true compensatory atrophy, although it is not impossible that the gonads of such

immature males produce so little—if any—androgen that the treatment may be regarded as "masculinization" of a neutral type.

Experiments on 6 castrate male and 6 spayed female 1 month old albino mice with an average body weight of 22 Gm. showed that daily administration of 3 mg. of testosterone during a period of twenty days caused no change in the average adrenal weight of the males (3.7 mg.), but in the females the average weight of the organ decreased from 4.7 to 3.8 mg. ($P = 0.06$). Microscopic examination showed that irrespective of the adrenal weight the X zone disappeared under the influence of the androgen in both sexes (fig. 8).

These results indicate that androgens have a definite effect on the adrenal cortex, a conclusion which receives further support through the observations recorded in table 1, that dehydro-*iso*-androsterone is also active in decreasing the adrenal weight of the female rat.

PREVENTION OF VARIOUS TYPES OF HYPERTROPHY OF ADRENAL CORTEX BY MEANS OF STEROID HORMONES

Although early investigators who used impure preparations of estrogens obtained contradictory results,³⁸ Selye, Collip and Thomson³⁹ showed that crystalline estrone causes marked hypertrophy of the adrenal cortex in the rat, a fact which has since been confirmed for numerous other estrogens. It appeared of interest to establish whether this hypertrophy may be prevented by other steroid hormones. For this purpose a series of experiments was performed on albino rats. The average weight of the males was 154 Gm. and that of the females 109 Gm. All experimental animals were treated with daily doses of 300 micrograms of alpha-estradiol while the other steroid hormones were administered in daily doses of 2 mg. The daily dose of each of these com-

pounds was injected subcutaneously in 0.1 cc. of peanut oil during a period of twenty days. The results of the experiments are summarized in table 3. The table indicates clearly that progesterone, testosterone and desoxycorticosterone are all capable of inhibiting the estradiol hypertrophy of the adrenal in males in which estradiol induced a significant cortical enlargement. In the females, the adrenals of which are larger than those of the males under normal conditions, the 300 microgram dose of estradiol used in these experiments led to no statistically significant adrenal weight increase and consequently the other steroids could not show a significant inhibition.

The fact that the adrenal enlargement normally produced by muscular exercise may be prevented by cortex extracts has been demonstrated by Ingle.²⁴ My associates and I⁴⁰ found that desoxycorticosterone, testosterone and progesterone may also prevent the adrenal enlargement caused by various other damaging agents such as injections of formaldehyde and surgical shock. Since during the alarm reaction elicited by such stimuli as muscular exercise, trauma or toxic doses of drugs the pituitary responds with an increase in adrenotropic hormone production¹⁰ and the aforementioned steroids inhibit the elaboration of the adrenotropic principle by the pituitary, it is concluded that the inhibition of adrenal enlargement under these conditions is probably mediated by the hypophysis.

SUMMARY AND CONCLUSIONS

Experimental evidence indicates that both in the mouse and in the rat desoxycorticosterone acetate causes marked involution of the adrenal cortex. Histologically the atrophy of the cortical cells is very pronounced in all three zones, yet unlike the atrophy caused by hypophysectomy it is not particularly severe in the zona reticularis. Although it appears quite probable that the action of this cortical steroid is due to its ability to inhibit production of adrenotropic hormone, this observation is not easily reconcilable with such an interpretation. The cells of the adrenal medulla become vacuolized and show signs of degeneration in rats treated with desoxycorticosterone acetate.

In the gonadectomized male or female mouse the characteristic X zone of the cortex disappears under the influence of desoxycorticosterone acetate. Changes in the medulla are not readily detectable in this species.

Progesterone given in large doses also causes involution of the adrenal cortex in the rat and to a lesser degree in the mouse. This effect is evident only in females, and even in these much higher doses have to be administered to obtain an atrophy comparable to that caused by desoxycorticosterone acetate. The X zone of the mouse adrenal disappears in gonadectomized males or females treated with progesterone.

Androgens such as testosterone or Δ^5 -dehydro-isoandrosterone are also capable of causing involution of the adrenal cortex, again much more readily in females than in males. The disappearance of the X zone, which is obtained by androgens in gonadectomized mice, is not always accompanied by a measurable decrease in adrenal weight.

Estradiol causes much more pronounced hypertrophy of the adrenal cortex in male than in female rats. This effect is inhibited by the simultaneous administration of desoxycorticosterone acetate, progesterone or testosterone.

The atrophy of an endocrine gland caused by the administration of an excess of the hormone or hormones which it produces is regarded as the exact antithesis of the compensatory hypertrophy elicited by the hormone deficiency occasioned by partial extirpation of such a gland. For this mechanism of readjustment the term "compensatory atrophy" is suggested. It is essentially the same mechanism which in human pathology is responsible for instance for atrophy of the adrenal cortex if a tumor develops in the cortex of the contralateral adrenal gland. Experimental work shows that such compensatory hypertrophy may in some instances be produced by substances other than the main product of secretion of a certain endocrine gland. Thus atrophy of the testis has been elicited with estrogens or progesterone, atrophy of the adrenal cortex with androgens or progesterone, involution of the adrenal medulla with desoxycorticosterone acetate and the like. In these cases, one is dealing with a "transferred" compensatory atrophy. This phenomenon promises to be of clinical importance, since it may afford a means by which to decrease the activity of overfunctioning endocrine glands without having to administer additional amounts of a substance which is already produced in excess. Thus, for instance, the use of desoxycorticosterone acetate (a substance which is practically devoid of androgenic activity) in cases of adrenogenital syndrome in which there is an excess production of androgen in the adrenal may prove useful in inhibiting the faulty endocrine secretion of the cortex.

ABSTRACT OF DISCUSSION

DR. J. P. SIMONDS, Chicago: Some years ago Dr. O. E. Hepler, working in our department on fat tolerance in experimental hyperthyroidism, demonstrated both anatomic and physiologic evidence of compensatory atrophy. After dogs had been fed large doses of desiccated thyroid for several weeks the thyroid gland became so small that it was often difficult to find it. When such feeding was stopped, the cholesterol of the blood rose within two weeks to the high levels characteristic of myxedema and other forms of hypothyroidism. I should like to ask Dr. Selye if he has made any observations on the permanence of this compensatory atrophy.

DR. MILTON STEINBERG, Chicago: I would mention in connection with this paper that in all probability the results were mediated through the anterior pituitary; that the results were not directly through flooding the system with the hormone but through suppressing the pituitary. I think that this work should be checked by examining the anterior pituitary microscopically and should also be checked in animals with the anterior pituitary removed; I doubt whether the effect would be present in that case.

DR. HANS SELYE, Montreal, Canada: With regard to the permanence of the lesions, I experimented only with testosterone and found that its actions are still detectable months after injections were discontinued. However, I don't believe the change would be permanent in the true sense of the word and I suppose that after a still longer period recovery would ensue. With regard to the statement that the adrenal atrophy induced by steroid hormones is indirect and mediated by the pituitary, I should like to state that this is quite in accordance with my own opinion; in fact, I have experimental evidence to prove this point. It was shown that if a hypophysectomized rat receives sufficiently large doses of adrenotropic hormone to maintain the adrenal in a normal condition, none of the steroids mentioned are able to cause cortical atrophy. This, I feel, shows distinctly that the steroids act mainly, if not entirely, by depressing the adrenotropic hormone secretion of the hypophysis. The only observation which would seem to plead against this interpretation is that the microscopic appearance of the cortex following atrophy induced by testosterone or desoxycorticosterone differs from that seen in hypophysectomized rats, a fact illustrated by the lantern slides.

MULTIPLE BENIGN CYSTIC
EPITHELIOMA

REPORT OF TEN CASES IN ONE FAMILY

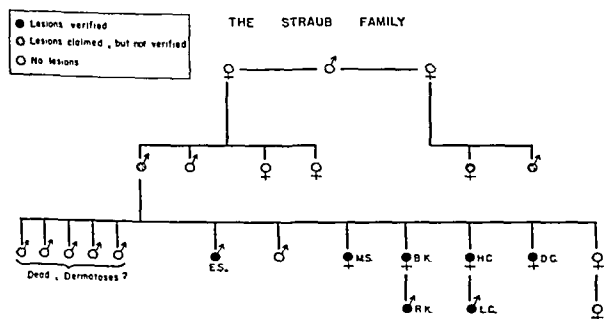

H. J. GOLDMAN, M.D.
ST. LOUIS

By this time the familial occurrence of multiple benign cystic epithelioma is a matter of general knowledge. As to the literature, the papers by Summerill and Hutton, by Sutton, by Beck, by Savatard and by Ricker and Schwalb supply sufficient details on the subject. A full bibliography appears in the articles by Summerill and Hutton and by Beck. The most extreme example was that of Sutton, who reported seventy-four cases in three generations. Of these, only one case was verified by biopsy; five were diagnosed by direct clinical examination and the remainder on hearsay. My own experience was made the more valuable because in seven of the ten cases a biopsy was secured—not only one specimen, but in one case three specimens and in three others two specimens. In short, twelve lesions taken from seven patients were studied. Thus it was possible to study, from one patient, a lesion from the angle of the nose, the forehead and the bridge of the nose and from another one from the lip and the scalp. This supplied an opportunity for comparison of lesions in one and the same patient as they occurred in different locations and to determine whether the processes were uniform in all the lesions.

It was a further stroke of good fortune that the family under study was a prolific one, numbering no fewer than sixteen members in the three generations affected by lesions. Moreover, the grandfather in the case had two wives, thus affording an opportunity to refer the hereditary factor to him and establish its transmission through two separate lines.

TRANSMISSION

The incidence of the condition in this family was 60 per cent. Whereas at first it was transmitted from the male to females, on subsequent occasions it was passed through the female. That is, there was not any consistent sex factor in the transmission of the disease.

MULTIPLE BENIGN CYSTIC EPITHELIOMA

Fig. 1.—The family tree.

The ratio of males to females was 5 to 5. Most strikingly, of seven brothers and sisters in the third generation whom I was able to study, five were affected.

Read before the Section on Dermatology and Syphilology at the Ninety-first Annual Session of the American Medical Association, New York, June 14, 1940.

From the Laboratory of Dermatological Research, University of Pennsylvania School of Medicine and the Graduate Hospital of the University of Pennsylvania.

HISTORY OF CASES

Mary S., aged 30, had distribution of the lesions as illustrated in figure 2. In addition there was a solitary lesion on the left shoulder. The disease began at the time of puberty. This case has been reported in full by Weidman and Besancon.¹ The lesion from in front of the ear exhibited the microscopic appearance of tricho-epithelioma, whereas the one from the shoulder exhibited syringo-adenoma.

Elmer S. (brother of Mary S.), aged 34, has had the disease twenty-five years. The distribution is indicated in figure 3.

Fig. 2.—Distribution of lesions in the seven cases. Mary S. had a solitary syringo-adenoma on the left shoulder in addition. Note the large lesion on the scalp of Russell K.; there were also lesions back of the ear.

A lesion from in front of the ear exhibited the microscopic appearance of tricho-epithelioma. There were numerous large keratinous nests. The same order of process was exhibited in a lesion from the angle of the nose. Incidentally, the cells in the first lesion contained much fine granular pigment.

Mrs. Dora C., aged 32, the married sister of Mary S. and Elmer S., had onset of the condition at puberty. Three specimens of lesions were secured. In those from the angle and the bridge of the nose the picture was identical, featuring numerous keratinous nests (probably dilated hair follicles). Foreign body granulomas were also present. In the third lesion, from the forehead, the picture was essentially that of a basal cell cancer, with one exception. Thus many of the

1. Weidman, F. D., and Besancon, J. H.: Histologic Differences in a "Syringoma" of the Face and Shoulder: Employment of Wax Reconstruction. Arch. Dermat. & Syph. 21: 279 (Feb.) 1930.

but this point cannot be stressed because the pigmentation did not occur consistently in the sections of my series.

In addition to the commonly postulated sites of predilection for lesions, the region in front of the ear should be noted.

4500 Olive Street.

ABSTRACT OF DISCUSSION

DR. FRED D. WEIDMAN, Philadelphia: Beginning with the discovery of one of these patients, Dr. Goldman was led to a good deal of detective work, whereby he was able to follow down the rest of the family. As a result, a rather unusual experience was met; namely, no less than 12 specimens were secured for biopsy from no less than 7 different patients. To some extent, different histologic pictures were met, and yet all of them came from the same biologic strains; that is, brothers and sisters. It seemed reasonable, therefore, to assume that all of the pathologic processes were biologically similar and, as a matter of fact, clinically they were the same entities. They were not basal cell cancers; clinically they behaved like multiple benign cystic epithelioma. That gave an excellent opportunity for reconciling and comparing the biologic with the morphologic aspects. Too much dependence cannot be placed on the microscopic appearance in appraising the biologic phenomena in the situation, which at once brings up a most practical consideration. The conclusion is, as shown by the last photomicrograph in Dr. Goldman's presentation, that a lesion which microscopically appears to be basal cell cancer is not cancer at all—at least biologically. Let me illustrate this lesson by an example. Suppose one encounters a solitary lesion clinically in which most of the microscopic picture is that of basal cell cancer. What is one going to do to determine whether the prognosis is going to be that of basal cell cancer or that of multiple benign cystic epithelioma? This is the crux; namely, that search should be made for evidence of these keratinous nests. If they are large and conspicuous, there is no difficulty at all; the matter is settled. Such nests indicate a relationship with tricho-epithelioma and from that a benign prognosis. It may be that instead of the nests being large they will be small and may have to be searched for. It may be that one would have to examine sections from different levels of the same paraffin block and perhaps it would not be a bad policy in all of our cases of basal cell cancer to examine sections from several different levels of the block in order to determine whether any of these telltale collections of keratinous material are here or there. If one finds them, the prognosis is better. If they are not found and if reasonable care has been taken to secure an examination of different levels—that is, representative positions in the same lesion—then, and then only, can one assume that the diagnosis is basal cell cancer and that therefore the less favorable prognosis must be added.

DR. HAMILTON MONTGOMERY, Rochester, Minn.: I agree essentially with what Dr. Weidman has emphasized. A few years ago Dr. A. E. Ingels in a case report (*Epithelioma Adenoides Cysticum with Features of Syringoma*, *Arch. Dermat. & Syph.* 32:75 [July] 1935) demonstrated all types of transition between epithelioma adenoides cysticum, tricho-epithelioma and syringoma. I have seen other cases in which there were similar transitions to cylindroma. Nomland reported a case that clinically resembled multiple benign pigmented nevi but histologically was frank basal cell epithelioma. Krompecher's concept of a basal cell origin for a basal cell cancer is generally accepted. There is a predilection for involvement of the forehead and nose and inner aspects of the cheek in both malignant and benign types of basal cell epithelioma. McDonagh called attention to the fact that many mammals, especially deer, have specialized hairs in the orbital facial fold, and explained basal-cell epithelioma on the basis of the lack of need of things that are present in the lower animals, and on the basis of hereditary cell rests. Glasunow expressed the opinion that basal-cell epithelioma on the face commenced in and about the lines of fusion of the embryonic facial processes. Paljtschewsky emphasized that basal-cell growths appear in areas which are well supplied with sebaceous glands and often

arise from comedones or nevi. Mallory has always championed a hair matrix origin for all types of basal-cell epithelioma. Neither in benign nor in malignant types of basal-cell epithelioma have I been able to demonstrate origin from the hair matrix cells. In the benign types, origin from the outer sheath of the outer hair follicles is frequently demonstrable and therefore one may speak of tricho-epithelioma or multiple benign cystic epithelioma. The ordinary basal cell cancer (basal cell in crypts), on the other hand, shows multiple points of origin from the basal cells of the epidermis. The same may be true in some instances of multiple benign cystic epithelioma and even is applicable to cylindromas.

DR. HERMAN GOODMAN, New York: It is conceded that the single layer of fetal ectoderm becomes the basal layer cells, which in turn, through chemical and physical changes, pass through the phases of squamous cells and corneum cells. The variations of the primary ectodermal layer become hair follicles, and so on. In facial blemishes, we have record of no less than thirty-seven supposed different types of lesions which arise from the ectodermal layer. Facial skin blemishes, for the greater part, are harmless clinically. Thousands of people receive treatment at the hands of barbers, beauticians and cosmetologists for facial skin blemishes. Rarely, if ever, is an ill effect reported. It becomes confusing, therefore, to have the terminology of skin cancer or cancer applied as a symptom or as a word in the same paragraph as epithelioma when it is utilized for benign cystic epithelioma. This presentation is the beginning of an orderly manner of continuing our studies in dermatology.

DR. DAVID BLOOM, New York: With regard to the question of heredity and family investigation, the paper by Dr. Goldman gives a hint of the value of this method. Of course, the study of one family tree in regard to a disease does not give exact information. But the study of many families with the disease and, particularly, twin studies may bring out facts which no other method of investigation has brought out until now. In dermatology there are a great number of problems which wait solution and which will probably not be solved unless newer methods of investigation are employed. I believe that cultivation of genetics in dermatology will contribute to the solution of many unsolved problems as to the etiology of disease.

DR. RICHARD L. SUTTON JR., Kansas City, Mo.: One must not be too certain of the benignancy of benign cystic epithelioma. In two cases that I have seen each of the many little tumors after having persisted for a long time in a harmless state has grown, producing a slowly progressive lesion, waxy, translucent, of hazelnut size, making a curious and typical picture. The face is grossly distorted, almost as if by nodular lepromas, with eventual ulceration. Such cases with thirty or forty progressive basal cell carcinomas at one time are difficult therapeutic problems. I have seen cases in which a lesion arching over the ear like a linear nevus, preauricular and extending upward, consisting of these little waxy pimples, took on active growth. One removes a mass of skin, including what one thinks is all of the tumor-bearing tissue; a year or two later at the upper end of the scar one removes a recurrence, and shortly one does the same thing still farther up the side of the head. Carefully questioned, practically all patients who have basal-cell carcinomas will tell, if they are observant, that the lesion began with a tiny, waxy pimple, which they thought was a blackhead and which they squeezed. Thereafter it grew. The question arises then whether their squeezing this lesion (which I presume was an epithelioma adenoides cysticum—it answers the description accurately) whether trauma changed the cell type; or did it simply translocate cells which were already potentially malignant and place them into more favorable environmental surroundings where they could grow? I think malignancy involves time considerations and that it is not possible to detect it solely by microscopic study of dead tissue. It is the prerogative only of the clinician to recognize malignant behavior, and the pathologist's original percept of whether a lesion is benign or malignant is accomplished by clinical observation. Malignancy is not a morphologic state. Many a lesion that microscopically looks

malignant isn't. Some that seem to be benign prove eventually not to be. It is only with the passage of time and as a lesion changes that one can know whether it is malignant or not.

DR. HYMAN J. GOLDMAN, St. Louis: With regard to Dr. Bloom's remarks about studying the heredity, he is right. We were inconvenienced somewhat by not being able to check up on many members of the family who could not be reached, some of them by reason of having been dead for many years. Dr. Sutton's remarks are applicable. The possibility of malignant degeneration has been discussed for many years and no definite conclusions reached. Of course, his remarks about a waxy pimple having finally turned into cancer, the waxy pimple being the description of the patient, are answered somewhat by S. Beck in his article in the Jadassohn handbook, in which he says that the only conclusive diagnosis in regard to multiple benign cystic epithelioma is the histologic one.

PRIMARY LESIONS OF THE JEJUNUM

DONOVAN C. BROWNE, M.D.
AND
GORDON McHARDY, M.D.
NEW ORLEANS

In 150,952 privately studied hospital admissions at Touro Infirmary (1926-1939) including 1,810 autopsies and 1,010,711 (1906-1939) cases at Charity Hospital of New Orleans with 6,160 (1936-1939) postmortem observations, primary pathologic changes of the jejunum were illustrated in a single instance each of traumatic regional enteritis and of intussusception, sixteen cases of diverticula, four perforated ulcers and eleven neoplastic involvements, of which seven were benign and four malignant.

This survey indicates an almost inconceivably low incidence. Yet the publications of recent years show increased cognizance of lesions of the small intestine. The number of case reports suggests either an increased incidence, the trend to report unusual pathologic conditions or diagnostic acumen. A study of the individual cases, however, reveals that only obvious lesions have been diagnosed by the clinician and roentgenologist. In many instances the establishment of the diagnosis came as a surprise to the exploring surgeon; most awaited necropsy study.

A proper concept of the anatomy and physiology of the jejunum coupled with an adequate evaluation of symptoms may increase the incidence of clinical diagnoses.

A review of reported symptomatology indicates three pertinent manifestations:

1. Pain is periumbilical or to the left and below the umbilicus, less frequently epigastric. Related to the site of the lesion it occurs at intervals after meals; the most proximal lesions cause almost immediate pain. The severity varies from quantitative discomfort in partially obstructive lesions to sharp pain when there is ulceration.

2. Obstruction is generally held to be an "all or none" phenomenon for jejunal lesions. This is inevitably so in primary intussusception and frequently so in neoplasms, especially the polypoid type, which produce intussusception in from 23 to 30 per cent of cases.

Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the authors' reprints.

Read before the Section on Gastro-Enterology and Proctology at the Ninety-First Annual Session of the American Medical Association, New York, June 13, 1940.

From the Department of Medicine, Tulane University of Louisiana School of Medicine, the Department of Gastroenterology, Touro Infirmary, and the Charity Hospital.

This is perhaps the earliest, most frequent and most diagnostic manifestation of a jejunal neoplasm. However, jejunitis in its degrees, ulceration, diverticulosis with associated inflammation and encroaching neoplasms may produce intermittent mild and progressive blockage, depending on the mechanical nature of the pathologic condition.

3. Inanition and anemia, due to physiologic and mechanical derangement rendering nutritional absorption defective or the result of chronic blood loss, is prominent in the protracted case.

In an effort to strengthen our diagnostic armamentarium roentgenologists Pendergrass,¹ Cole,² Chamberlain³ and others have made stimulating investigations on the small intestine. Reviewing radiologic failures with the present routine (fluoroscopy, immediate and six hour films) one finds the accuracy in proved instances to be less than 50 per cent for jejunal neoplasms and

Fig. 1.—Jejunal delineation with barium sulfate enteroclysis.

10 per cent for jejunal diverticula; studies are negligibly positive in primary jejunal ulcers and jejunitis. Various types and thicknesses of contrast medium have been used. Miller-Abbott⁴ intubation studies and barium sulfate enteroclysis suggested by Gershon-Cohen and Shay have resulted in excellent physiologic, chemical and radiographic observations. The incidence of jejunal pathologic changes does not warrant the adoption of any of the thorough methods of roentgenologic investigation of the jejunum as a routine; this would be too costly and too time consuming. Two and four hour films taken as a routine have not proved of value. The radiologist therefore awaits the internist's alertness to request studies when indicated. When the need

arises it seems likely that intubation and barium sulfate enteroclysis offer a more satisfactory mucosal delineation both as to time and as to completeness of examination, than any other method.

This presentation covers pathologic conditions which are truly primary to the jejunum, with omission of congenital defects. Bovine tuberculosis may occur primarily in the gastrointestinal tract, but necropsy studies have not shown even an isolated instance in which the jejunum was the primary site. Avitaminosis, by producing mucosal edema and motor and nerve derangement, may lead to secondary changes in the tract, producing roentgenologically distorted mucosal patterns, localized distentions and barium stagnation. Hypermotility of the small intestine is a frequent occurrence in association with instances of functional dyspepsia. Purely functional disorders, dilatation associated with migraine and other such vague entities are difficult to establish on a sound clinical basis.

INTUSSUSCEPTION

Intussusception in the jejunum represented only 0.9 per cent of 3,784 cases of intussusception reviewed by Freilich and Coe.⁵ While only 5 per cent of all intussusceptions occur in adults, the jejunal type is more common to adult life than to childhood and is usually

A study of the literature since Crohn's initial publication reveals more than 600 cases of regional ileitis but the surprising recording of only twenty instances of jejunal involvement. Wilensky⁹ has ably covered the subject of etiology and was unable to ascribe the pathology to any one original cause, and he therefore concluded that it is an attempted overproductive but unsuccessful healing of a nonspecific lesion.

Through extensive studies of regional enteritis a definite correlation of the clinical manifestations with the pathologic process through four stages of the disease seems established. These studies are applicable to jejunal involvement:

1. The first phase is a state of acute inflammation with a thickened red, leathery, edematous bowel showing slight serosal exudate. The clinical picture may be that of acute appendicitis with the exception that there may be accompanying diarrhea, poor localization of pain and higher febrile rise than is expected in uncomplicated acute appendicitis. Differential diagnosis without laparotomy is not possible and its establishment as an entity is the result of careful exploration at the time of an appendectomy on a patient whose appendix does not substantiate the preoperative diagnosis of acute appendicitis.

TABLE 1.—Thirty-Four Cases of Primary Pathologic Changes of the Jejunum

	Touro Infirmary	Charity Hospital	Method of Diagnosis			Symptomatology					Average Age	Sex	
			X-Ray	Surgery	Autopsy	Obstruction	Pain	Perforation	Anemia	None		Male	Female
Admissions studied.....	150,032	1,010,711

secondary to a neoplasm. Ryan and Morgan⁶ reported a case which they considered primary, but there had been a previous gastro-enterostomy, which probably was related to the accident. In childhood the jejunal type is extremely rare, usually occurs without demonstrable cause and is therefore properly termed primary jejunal intussusception. In Freilich and Coe's series there were only four instances in twenty-nine cases of jejunal intussusception. The pathology of acute intussusception is the same regardless of the type and location. Clinically there are the dramatic manifestations of severely painful high intestinal obstruction. A palpable abdominal mass and bloody mucoid defecation occur in 25 per cent. Immediate surgical correction is indicated.

JEJUNITIS (REGIONAL ENTERITIS INVOLVING THE JEJUNUM)

Localized inflammatory lesions of the small intestine designated as nonspecific granulomas or inflammatory tumors have long been known. Crohn⁷ reactivated interest in the entity with his 1932 publication in which he coined the term "terminal ileitis," attempting to differentiate on an anatomic basis what he then believed to be a disease state peculiar to that segment. Harris and his collaborators⁸ brought recognition to enteritis at higher levels, reporting an instance in which the same pathologic process was found in the jejunum.

We suggest conservatism at this stage, i. e. a diagnostic exploration. The pathologic process is expected to subside spontaneously. The lesion may progress to stages of chronicity, but still this premise is not adequate to indicate radical thought. The major corrective procedures (enterocolostomy, enterostomy, resection) carry a measurable risk, and recurrences in a normal segment may occur after wide resection. Time and statistics may change our present conclusions.

2. Subacute or chronic nonulcerative enteritis is a progressive state which may show periods of remission. Abdominal distress, mild diarrhea, slight febrile reactions, leukocytosis and melena have persisted. Roentgenologically there are segments showing smooth contour with uniform narrowing and spasm. This and subsequent states are surgical problems.

3. Chronic ulcerative enteritis shows additional manifestations of moderately severe anemia, obstruction and melena; there may be a palpable tumor. X-ray examination shows irregular outline and caliber, with some loss of flexibility and changes in the mucosal pattern simulating ulcerative colitis.

4. The hyperplastic stage is an advanced state of the pathologic process with apparent inanition and marked obstructive manifestations suggestive of the clinical appearance in far advanced ulcerative colitis. A radiographic study reveals obliteration of normal outlines, loss of flexibility, shortening contraction of the lumen with stenosis and occasionally fistula formation.

5. Freilich, E. B., and Coe, G. C.: *Ann Surg.* 105:183 (Feb.) 1937.

6. Ryan, T. F. J., and Morgan, W. P.: *Brit. M. J.* 1:613 (March 25) 1939.

7. Crohn, B. B.: *Am. J. Digest. Dis. & Nutrition* 1:97 (April) 1934.

8. Harris, F. I.; Bell, G. H., and Brunn, H.: *Surg., Gynec. & Obst.* 57:637 (Nov.) 1933.

9. Wilensky, A. O.: *Surgery* 6:288 (Aug.) 1939.

There is a tendency to reason in the treatment of enteritis of the jejunum as one does in that of ulcerative colitis, i. e., to reserve radical surgery for the rapidly progressive instances which do not respond to every effort at conservatism but to act before the damage is too far advanced to expect results.

Regional enteritis manifest subsequent to severe abdominal trauma has been reported by H. E. Mock¹⁰ in three cases and by Bargen and his associates¹¹ at Mayo Clinic in two. In symptomatology, surgical aspects and pathology the lesions were those of regional enteritis. A single instance of such a coincidental jejunitis was encountered in our review of cases at Charity Hospital, and an abstract is included at the end of the paper.

DIVERTICULUM IN THE JEJUNUM

Diverticula in the jejunum, while still anatomic curiosities, are statistically the most prevalent primary jejunal lesions. Roentgenologically, Case¹² records the incidence to be 0.1 per cent; at autopsy instances are encountered in about 0.5 per cent of cases, according to a Johns Hopkins review. The cases are classified as congenital when the sac is made up of the same layers as the normal jejunal wall. Acquired herniations of the mucosa through the muscle layer are covered only by serosa. They are subject to inflammatory changes of diverticulitis and rarely perforate.

Etiologically they seem to be a product of degenerative changes, the greatest number being demonstrated in advancing age. The anatomic defect at the site of penetration of the blood vessels into the intestinal wall near the mesenteric attachment results in a point of decreased resistance which is subjected to irregular intestinal contractions that increase the intra-intestinal pressure. Charles Mayo¹³ observed a diverticulum form, during an intestinal operation, while the proximal bowel segment was in a state of contraction. The acquired diverticulum may be due to traction of some neighboring inflammatory process, as is contended by Fletcher and Castlenden. Multiplicity is characteristic.

Jejunal diverticula are considered innocuous; careful study of 100 cases reveals related symptoms in 35 per cent. Postprandial epigastric or left hypochondriac pain, flatulence, heartburn, occasional mild obstruction and melena have been accredited to their presence. By disturbance of function of the small bowel they may produce vitaminotic and nutritional deficiencies. Diverticulitis is infrequent because of the liquid contents and the free communication between the sac and the intestinal lumen. Perforation is rare. Watson¹⁴ reported jejunal obstruction caused by the weighty traction of an enterolith in a diverticulum.

Roentgenology offers the only preneecropsy method of diagnosis aside from surgery. Rankin and Martin,¹⁵ in reviewing 100 surgically proved cases found an x-ray diagnosis in only 10 per cent, substantiating the contention that jejunal diverticula are more often diagnosed during operation than by radiography.

Therapeutically, surgery is the only corrective measure available. Medically, dietary restriction and

measures aimed at avoidance of increased intra-intestinal pressure are offered. In the absence of clinical symptoms their removal is not justified. The severity of symptoms and the occurrence of complications indicate the need for surgical intervention. Resection, simple excision or a side tracking anastomosis are operative offerings.

CASE 1.—J. T. T., a white woman aged 69, was first seen at the age of 50 with discomfort in the lower part of the abdomen associated with constipation. Gastrointestinal studies then showed evidence of ileocecal adhesions (postappendectomy) with barium sulfate not yet in the cecum in the six hour film. When reexamined at the age of 60, free from gastrointestinal symptoms, a check gastrointestinal series showed, in addition, a single duodenal diverticulum. In 1939 she returned complaining of periumbilical pain about an hour after meals, waking her from sleep in the early morning. There were associated progressive asthenia, a slight loss of weight, anemia and mild hypovitaminosis. The patient was anemic and of small asthenic proportions, with skin and mucous membrane signs of vitamin deficiency. A radiographic study at this time revealed a single duodenal diverticulum and two diverticula in the jejunum.

Fig. 2.—Jejunal diverticulum.

A medical regimen consisting of a bland high caloric, high vitamin diet with frequent feedings and supplemental vitamins, aluminum hydroxide, sedatives and antispasmodics has not alleviated the symptoms.

This case reveals the development of diverticula in an aging patient who had a source of increased intra-intestinal pressure. The symptoms seem to be quite definitely related to the development of this pathologic picture. Operative correction seems to be the only recourse for relief, but the patient's aversion to surgery has delayed such therapy.

ULCER

Primary jejunal ulcer is a rarity. We have been able to find seventy-six reported instances since Rufz's initial publication on the subject in 1843. Apparently, this portion of the small intestine is resistant to ulceration. After gastro-enterostomy the jejunum loses its relative immunity, for marginal ulcers are frequently encountered. Our gastroscopic observations indicate that the majority of these occur in gastric mucosa at the anastomosis.

In the limited study of primary jejunal lesions the etiology is even more obscure than in gastroduodenal ulceration. Theoretically, dystopic rests of the gastric mucosa may exist. The alkalinity of the jejunum is significant; gastric acidity could hardly be a factor in the development of an ulcer beyond the ligament of Treitz. Distant foci of infection, syphilis, tuberculosis, vasomotor phenomena and precedent jejunitis have an established position in the etiologic consideration. "Inherent predisposition" seems to have a place here as in the relation to the incidence of gastric and duodenal ulcers and leaves one with the conclusion that the cause of primary jejunal ulcer is unknown.

Pathologically the ulcer is a circular lesion varying from 4 mm. to 2 cm. in diameter; only 15 per cent are annular. Thickening, induration, stenosis and chronicity are prominent. The proximal portion of the jejunum is the portion of predilection, 72 per cent occupying such a site. All occur opposite the mesenteric attachment. A single ulcer is encountered in 80 per cent of cases, multiple ulcers are present in 18 per cent and associated gastric or duodenal lesions are expected in only 2 per cent. Some degree of penetration is usually present; in 82 per cent of the cases there was actual

Fig. 3.—Jejunal ulcer.

perforation. Hemorrhage is recorded in 23 per cent of the cases and in all but six of these perforation also occurred. Microscopic examination revealed changes of chronic inflammation; no instance of malignant change was proved.

There is no clinical picture. Vague dyspeptic symptoms may bear slight resemblance to the "duodenal ulcer syndrome." Pain around the umbilicus or in the lower part of the abdomen is expected. If melena occurs one might expect the stool to be a cherry red. As with other pathologic changes in the small bowel, degrees of inanition and hypovitaminosis are prominent. Because of the fluid consistency of the jejunal contents, obstructive manifestations are not expected unless there is marked stenosis. Perforation results in an acute condition of the abdomen without specific localization.

Diagnosis is possible if the patient is available for radiographic study and there is sufficient suspicion to indicate delineation of the small bowel. A niche on the antemesenteric border of the jejunum with stasis proximal to the lesion is significant. A presurgical or antemortem diagnosis cannot otherwise be established.

Because of a statistical mortality of 60 per cent and the tendency to perforation, surgical intervention is the only logical therapy. There is no rationale for conservatism. Simple plication or radical resection is a matter of surgical judgment at the time of exploration.

CASE 2.—J. I., a white youth aged 19, was admitted, Nov. 23, 1939, with an acute condition within the abdomen of four days' duration. Five months previously he had attacks of colicky pain in the left inguinal region and mild postprandial discomfort in the upper part of the abdomen. An ambulatory regimen for ulcer gave no relief. In a three month interval he lost 25 pounds (11.3 Kg.). Two months prior to admission he experienced a three day period of diarrhea, profound weakness, umbilical pain and cherry red stools. This time his physician ordered a bed rest regimen for ulcer. From this time on he suffered almost constant pain in the left lower quadrant and had repeated episodes of emesis.

Four days before admission he experienced sudden severe pain in the left midsection of the abdomen which radiated to become periumbilical and later localized in the appendical area. There were associated emesis, a sharp febrile rise and a tendency to loose stools with progressive abdominal distention.

When examined the patient was acutely ill and febrile. The abdomen was distended symmetrically. There was acute tenderness in the right lower quadrant with poorly localized marked rigidity. One gained the impression of a thick edematous parietal peritoneum. No mass could be felt.

The leukocyte count was 22,000 with 93 per cent neutrophils. Flat and upright films of the abdomen were negative.

On the basis of these observations a diagnosis of a perforated hollow viscus was made, probably Meckel's diverticulum or appendix. The surgical consultant felt that the duration of the symptoms might well fit abdominal tuberculosis or Hodgkin's disease and advocated further observation.

The patient was treated conservatively with transfusions, Wangenstein suction, parenteral fluids, vitamins and alcohol. The Wassermann reaction, tests for agglutination and blood and stool cultures were repeatedly negative. Gastric analysis showed 21 units of free hydrochloric acid. The patient's condition became progressively worse with inanition and hypoproteinemia (serum proteins totaled 4.25 mg. per hundred cubic centimeters). Later he exhibited definite ileus despite from five to seven watery stools daily. Confirmatory x-ray examination also revealed free air and fluid intraperitoneally. Exploratory laparotomy revealed a perforated jejunal ulcer 24 inches beyond the ligament of Treitz. This was plicated.

On the second postoperative day pulmonary and renal infarcts developed and the patient died.

Autopsy revealed, in addition to generalized peritonitis, pulmonary and renal infarcts and the sutured jejunal ulcer another perforated jejunal ulcer 3 inches beyond the ligament of Treitz, which was oblong and measured 2 by 1 cm. Microscopic sections revealed only chronic inflammatory changes.

We cannot elicit any etiologic hint from this study. It is well illustrated that in this case a conservative medical regimen for ulcer was of no benefit. Earlier surgical intervention might have been of value.

NEOPLASM

Neoplasms primarily involving the jejunum are not as infrequently encountered as is generally thought. The actual number of cases diagnosed cannot be accurately determined, since tumors of the three divisions of the small intestine are summarily dealt with in autopsy and operative statistics. We reviewed 485 malignant and 170 benign lesions of the jejunum.

These new growths may be benign or malignant. It is confusing that carcinoids fall under both classifications. Their relative incidence is indicated by Raiford's¹⁶ investigation of 11,000 autopsies and 45,000 surgical specimens revealing eighty-eight tumors of the small bowel, of which fifty were benign and thirty-eight malignant. Our statistical study, however, shows that malignant lesions were more frequent than the benign type. Adenoma is the commonest benign tumor, carcinoma the most frequently encountered malignant growth.

16. Raiford, T. S.: *Radiology* 16: 253 (Feb.) 1931; *Am. J. Cancer* 18: 803 (Aug.) 1933; *Arch. Surg.* 25: 122 (July) 1932.

Etiologically it is postulated that the fluid alkaline contents with the absence of stasis explains the infrequency of malignant growths. There is no report of a chronic ulcer undergoing neoplastic change. That changes in Brunner's glands and in aberrant gastric and pancreatic tissue are etiologic factors is insignificant and, further, lacks substantiation.

Predilection does not favor the jejunum in the occurrence of neoplasms of the small bowel. An analysis of

134 cases shows the duodenum predominating with fifty-one, the ileum next with forty-four and the jejunum next with thirty-nine instances.

The clinical picture is essentially the same for all neoplasms. Their differentiation is solely on a histologic basis. Flatulence, malaise, postprandial pain relieved by vomiting, asthenia and loss of weight and progressive anemia are the indefinite manifestations which occur in various degrees and combinations to precede obstruction which may be partial, recurrent, progressive or acutely complete. In adult life a neoplasm of the small bowel is the most frequent cause of intussusception. Each type of lesion has been reported as a cause, the polypoid type, of course, being the more frequent offender.

The nonoperative establishment of a jejunal neoplasm is difficult. Typical radiographic signs would be (1) dilatation of the proximal portion of the bowel with abnormal barium sulfate retention, (2) jejunal filling defect, (3) point of intestinal obstruction, (4) a dense shadow.

Surgical resection is the only curative method of management, whether the lesion is benign or malignant, for the former are certainly malignant by position and potentiality. When resection is not possible a short circuiting entero-enterostomy is the only alternative. High voltage roentgen therapy has a position of doubtful value.

Carcinoma primary to the jejunum is well established in 234 instances appearing in the literature. The relative incidence is illustrated by eight jejunal carcinomas reported from the Mayo Clinic as compared to 2,513 gastric and 2,767 rectal involvements.

The most common carcinomatous lesion is a polypoid stenosing type in favor over the annular ulcerating growths 3:1. The intestinal wall is not deeply involved until late, so that perforation is rare. It is significant that metastases are found in only 35 per cent of cases at the time of operation.

Sarcoma occurs in the small intestine more frequently than in the large bowel segments by a ratio of 2:1, as shown in Ullman and Abeshouse's¹⁷ review. The ileum is supposedly more often involved than the jejunum because of the greater amount of lymphoid tissue in this segment. Aneurysmal dilatation is a prominent occurrence related to either muscularis infiltration or to nerve plexus destruction. Sarcomatous lesions include lymphosarcoma, leiomyosarcoma, fibrosarcoma, neuro-

fibrosarcoma and melanosarcoma in relative frequency as listed.

Lymphosarcoma of the jejunum was found in sixty-nine cases. Starting in the lymphoid follicles, the wall is infiltrated, ulceration is characteristic and perforation results in 14 per cent of cases. Stenosis is rare, not occurring unless there is a considerable resultant fibrosis.

Leiomyosarcomas form a group of forty-two reported instances. They occur as circumscribed projecting oval tumors in half the cases and as an infiltrating mass in the other half. Showing a tendency to grow outward to the mesentery, they seldom cause obstruction.

Fibrosarcomas in twenty reports were either circumscribed or bulging with central necrosis and ulceration. As the entire wall is involved, stenosis is frequent.

Neurofibrosarcoma occurring as a primary jejunal lesion in eight cases presented no characteristic manifestation.

Melanosarcoma has been reported in three instances of jejunal involvement.

Malignant carcinoids or argentaffin tumors in the jejunum consist of nine instances found in 238 cases of involvement of the small bowel reported since Abernethy in 1907 differentiated these neoplasms from carcinoma. Their benignancy stressed by Forbus is disproved by more recent studies revealing metastases in 25 per cent of cases. Occurring as small submucosal nodules, they may bulge into the lumen as polypoid projections or may assume an annular form with fibrotic reaction.

Soresi¹⁸ and Sears¹⁹ each reported an instance of primary chorionepithelioma.

Cabot case 25242²⁰ was a malignant lymphoma of the jejunum.

Benignancy of jejunal lesions is only a histologic state and as such, aside from lipomas and enterocysts, is probably only a temporary condition. The occurrence of lipomas and enterocysts in the jejunum represents 25 per cent of benign tumors of the small bowel. Table 3 shows the relative frequency of benign tumors in 170 cases.

Variations between tumor types have been classified under the most closely related cell derivation. Multiplicity is common for hemangiomas and carcinoids; the other benign tumors more commonly occur singly. Their derivation is histologically apparent except for the enterocysts. Enterocysts may be the result of

TABLE 3.—*Benign Tumors (170 Cases Reviewed)*

pinched off diverticula or detached epithelium from the embryonic intestine. They consist of an epithelial mucosa, a thin connective tissue submucosa and a muscularis of two layers. The content is a pale clear albuminous alkaline fluid. Occurring in the submucosa, muscularis, subperitoneal region and mesentery, they may occasion volvulus, intussusception and stenosis.

18. Soresi, A. L.: *Am. J. Cancer* 28: 583 (Nov.) 1936.

19. Sears, J. B.: *Ann. Surg.* 97: 110 (June) 1933.

20. Cabot Case 25242, *New England J. Med.* 220: 1008 (June 22) 1939.

17. Ullman, Alfred, and Abeshouse, B. S.: *Ann. Surg.* 95: 878 (June) 1932.

Enucleation, resection, marsupialization and evacuation have been employed in their management, with the former two claiming more rationale.

CASE 3.—W. A. I., a white man aged 69, first seen Jan. 3, 1940, complained of postprandial periumbilical pain spontaneously relieved within a half hour. There were three occasions of emesis. He had lost 15 pounds (6.8 Kg.). A diagnostic survey, although not positive, suggested a lesion in the upper part of the gastrointestinal tract, and exploratory laparotomy was advised. The patient refused and was not seen again until March 16. In the interval he lost an additional 21 pounds (9.5 Kg.), and an exploratory examination was again advised. On the day of hospitalization the patient experienced melena for the first time.

Examination revealed evidence of inanition. There was a questionable movable mass in the left upper quadrant.

Gastric analysis showed hyperchlorhydria. There was marked hypochromic anemia and mild hypoproteinemia. Stools showed occult blood.

Fig. 4.—Jejunal lymphosarcoma (courtesy of Dr. Jerome Levy).

X-ray examination of the gastrointestinal tract revealed a wide sweeping curve of the duodenum with dilatation of the duodenum and proximal portion of the jejunum, barium sulfate retention and jejunal ulceration.

After adequate preparation an exploratory laparotomy was done revealing the proximal 30 cm. of jejunum enlarged and thickened, followed by an area of marked thinning studded with multiple nodules and perforated at one site. Jejunal resection, pyloric occlusion and gastrojejunostomy were successfully done.²¹

COMMENT

We present this review to bring attention to the importance of pathologic changes of the small bowel. Concentration of our study to the jejunum was stimulated by the fact that it is least often considered in a gastrointestinal survey. In our thirty-four case reports there is an indication that the more thorough study accorded the private patient increases the incidence in the private group.

21. Dr. Jerome Levy gave the authors permission to report his case illustrating a primary lymphosarcoma.

CONCLUSIONS

1. Primary pathologic lesions of the jejunum are relatively rare in contrast with other gastrointestinal lesions.

2. Clinical and roentgenologic diagnoses are infrequent; surgery and necropsy have revealed most of the instances that have been recorded.

3. Diagnosis is available by special radiographic technic, preferably enteroclysis, but such is not a practical routine procedure.

4. The clinician must become sufficiently aware of the entity to suspect its presence and request diagnostic x-ray examination.

ADDITIONAL ABSTRACTS OF CASES JEJUNITIS

CASE 4.—A Negro youth aged 21 seven days subsequent to severe abdominal trauma experienced umbilical and left lower quadrant cramping pain followed by quantitative dyspepsia and a severe sharp pain relieved by vomiting. There was mild diarrhea, melena and low grade fever. X-ray examination showed distention of the proximal portion of the jejunum. Exploratory laparotomy revealed a distended proximal portion of the jejunum with a thickened, acutely inflamed area in the midportion of the jejunum. A successful resection was done. The pathologic report was as follows: Six inches of jejunum had an acutely and markedly congested serosal surface. The thickened leathery wall showed acute exudative and chronic inflammatory changes. The lumen was constricted to 4 mm.

DIVERTICULA

CASE 5.—A Negro man aged 69 who had an acute condition within the abdomen and high intestinal obstruction refused surgery and died within four days. Necropsy revealed acute diverticulitis with perforation of a diverticulum 4 cm. beyond the duodenojejunal flexure.

CASE 6.—A white woman aged 36 complained of periumbilical pain and vomiting. X-ray examination showed barium sulfate stasis in the lower part of the jejunum with narrowing. Surgery revealed multiple diverticula in the lower jejunal segment; resection was successful.

JEJUNAL ULCERS

CASE 20.—A white man aged 58 complained of an acute condition within the abdomen of five hours' duration. Previous symptoms were suggestive of duodenal ulcer. The right lower quadrant was acutely tender. An exploratory operation revealed a perforated jejunal ulcer 12 inches beyond the ligament of Treitz. Resection and jejunojejunostomy were successful. Pathologic changes included 6 inches of jejunum and a perforated ulcer with chronic proliferative inflammatory changes.

CASE 21.—A Negro girl aged 5 years was markedly anemic with an acute condition of the abdomen and persistent vomiting. Cutaneous ulceration was present. *Ascaris lumbricoides* was present in the stool. The Wassermann reaction was negative. Autopsy revealed multiple perforated jejunal ulcers (mid-portion) but no specific microscopic abnormalities.

BENIGN TUMORS

CASE 23.—A white man aged 74 had a sudden onset of high intestinal obstruction. Autopsy revealed a jejunal lipoma causing intussusception.

CASE 24.—A Negress aged 49 had a sudden onset of high intestinal obstruction believed due to previous surgery. Autopsy revealed a fibroma of the jejunum contributing to high intestinal obstruction and acute kinking due to adhesions.

MALIGNANT TUMORS

CASE 30.—A Negro aged 39 complained of periumbilical pain, obstructive symptoms, diarrhea and loss of weight. An exploratory operation revealed an adenocarcinoma of the proximal portion of the jejunum with metastases to the omentum and regional lymph nodes. A palliative gastrojejunostomy was successful.

CASE 31.—A white man aged 56 with umbilical pain of three months' duration, loss of weight, malaise and anemia suddenly

experienced obstructive manifestations. An exploratory operation showed a jejunal neoplasm—not resectable—enterostomy. At autopsy an adenocarcinoma with metastases was found in the proximal portion of the jejunum.

JEJUNAL INTUSSUSCEPTION

CASE 34.—A white girl aged 14½ months suddenly manifested pain, a distended abdomen and bloody diarrhea. Autopsy revealed intussusception of the jejunum (no anatomic or pathologic cause was demonstrable).

1534 Aline Street.

ABSTRACT OF DISCUSSION

DR. DAVID ADLERSBERG, New York: The paper of Drs. Browne and McHardy proves the increased interest of the gastro-enterologist in lesions of the small bowel and represents a valuable contribution to our knowledge. It is important to realize and emphasize that the jejunum is the site of more extensive enzymatic digestion and absorption than any other part of the digestive tract; thus, pathologic changes of the jejunum are likely to impair the processes of digestion and nutrition to a great extent. It has been also my experience that definite periumbilical pain should call attention to the possibility of a lesion of the small intestine. Intubation with the Miller-Abbott tube and careful fluoroscopic and roentgenographic examination are time-consuming procedures but of essential diagnostic importance. It is agreed that organic lesions of the jejunum such as intussusception, diverticulosis and diverticulitis, primary jejunal ulcer, granuloma of the jejunum (regional jejunitis) and neoplasms (carcinoid, carcinoma, sarcoma and lymphosarcoma) are rare diseases in comparison with other pathologic changes of the gastrointestinal tract. However, it is my belief that milder changes of the jejunum of an inflammatory origin or on the basis of nutritional deficiency are not as infrequent as generally thought. Let me give one example: On gastroscopic examination of patients with gastric resection or gastro-enterostomy, one is frequently struck by the inflammatory changes of the stoma in its gastric as well as in its jejunal portion. In some of these cases the visible jejunitis is more impressive and probably more responsible for the patient's symptoms than the gastritis. One even wonders whether the jejunitis is not a precursor of a marginal ulcer in these cases. In other instances jejunitis cannot be diagnosed by direct visualization, yet an exact history of the case and a careful fluoroscopic and roentgenographic examination of the small bowel will possibly permit an indirect diagnosis.

DR. MAURICE FELDMAN, Baltimore: The roentgen demonstration of jejunal pathologic changes is often confusing because of the technical difficulties encountered in isolating the segments of the jejunum. The same difficulty, however, also holds true in the clinical diagnosis, particularly in the early cases. The information one obtains in the roentgen investigation of the jejunum is almost always the result of late manifestations of the disease. There can be no question that early abnormalities are being overlooked in the vast majority of cases. In this I am in accord with the authors. I should like to emphasize that early roentgen manifestations of disease of the jejunum may be radiologically depicted by a careful painstaking study of the mucosa of the different segments during the transit of the barium sulfate meal. I should like to ask the authors whether they have compiled their data to determine at what stage, particularly in carcinoma, it was possible to demonstrate the condition by means of the roentgen rays.

DR. DONOVAN C. BROWNE, New Orleans: We are all familiar with the work of Dr. Adlersberg on inflammatory lesions of the small bowel and our observations here are in no way contradictory. It is conceivable that such pathologic conditions may occur and especially are they impressive when one sees the changes proctoscopically which may occur in the rectosigmoid following acute infections of the upper respiratory tract. At what stage can the diagnosis of carcinoma be made? It is regrettable that at the time of diagnosis 30 per cent gave evidence of metastases and inoperability, stressing the need for more careful study of the small intestine. Unfortunately, adequate follow-up has not been available.

STILBESTROL-INDUCED GYNECOMASTIA IN THE MALE

CHARLES WILLIAM DUNN, M.D.

PHILADELPHIA

The therapeutic action of stilbestrol in the human being is under investigation by the Council on Pharmacy and Chemistry of the American Medical Association. This case is reported as a contribution toward defining its effect on the human species.

One of the established biologic effects of the naturally occurring estrogens is their growth-stimulating action on certain tissues and organs, one of which is breast tissue. It has also been experimentally established that when estrogenic substance is administered in sufficient amounts it has an inhibitory effect on anterior pituitary lobe trophic functions, among which are the production of growth hormone and the gonadotropic factor. A limited amount of clinical evidence supports these experimental observations.

I¹ have induced gynecomastia in males by administering the natural estrogenic substance. The tissue was studied and reported on by Dr. Charles F. Geschickter.² The production of breast development in the female by the administration of natural estrogenic substance has been reported by myself¹ and others. Premature breast development occurred in a girl aged 6 years with gonorrheal vaginitis treated with stilbestrol. Neither hypodermic nor suppository estrogenic therapy could be administered because of the child's physical resistance to these forms of treatment. The child was given 3 drops of stilbestrol solution (1 mg. per cubic centimeter) daily. After six weeks of stilbestrol therapy a mass approximately 2.5 cm. in diameter and 1 cm. in thickness appeared beneath the nipple in both breasts. At this period of therapy the vaginal discharge had disappeared.

I have observed marked breast development in young primary amenorrheal women treated with 5 mg. of stilbestrol daily for from fifty to sixty days. This is evidence that stilbestrol has a growth-promoting action on mammary tissue in the human female.

The present report concerns a male sexual criminal aged 27 years, now incarcerated, with a seven year history of repeated sexual offenses against minor females. Proper permission for the therapeutic experiment was obtained. The initial therapeutic objective in this case was to depress, if possible, the excessive and criminally directed sexual activity of the patient. That the excessive sexual activity was not the result of an increased activity of the so-called central nervous sexual center was indicated by the abnormally high urinary secretion of testis hormone and the gonadotropic factor. The assay report of his urine was 285 bird units of androsterone, 300 rat units of androsterone, 20 rat units of estrogen and 120 rat units of the gonadotropic principle of the urine of pregnant women or of placenta. The abnormally large penis and oversize testes, the sexual history and the hormone assay therefore indicated an anterior pituitary gonadotropic hyperactivity and a resultant increased activity of the testes and production of male hormone.

From the University of Pennsylvania Graduate School of Medicine.

2. Geschickter, C. F.: Breast Pathology in Relation to Endocrine Disorders in Piersol, G. M., and Bortz, E. L.: *Cyclopedia of Medicine, Surgery and Specialties*, Philadelphia, F. A. Davis Company, 1939, vol. 9, p. 549.

The patient was given orally 5 mg. of stilbestrol daily, beginning on June 20, 1940 and continuing for a period of sixty days, until a total of 300 mg. had been administered. Because a favorable and desired effect of therapy was obtained, 5 mg. of stilbestrol was then orally administered every other day for a period of thirty-six days. A total of 480 mg. of stilbestrol had been orally administered in a period of ninety-six days without evidence of toxic effect.

At the end of seventy-five days' therapy, when a total of 425 mg. of stilbestrol had been administered, the patient began to have sensitiveness in both nipples and observed a small lump beneath each nipple. During the subsequent twenty-one days the mass beneath the nipple increased progressively in size and sensitiveness and had become painful when he lay on the breasts.

The patient was examined at the end of ninety-six days of therapy, when a total of 480 mg. of stilbestrol had been administered. Physical examination revealed a hard, firm mass beneath the nipple of both breasts, the diameter of which was approximately 6 cm. and its thickness was approximately 2.5 cm. The edge and superior surface of the mass was freely movable beneath the skin, and the mass was separable inferiorly from the pectoral fascia. The mass was regular in outline, well defined and sensitive on palpation. Prior to therapy the breast region had been normal. The physical features of the gynecomastia produced in this male corresponded in character to the breast development produced in the young female child and young adult females to whom stilbestrol was administered.

In my opinion the mammary gland development resulting from the administration of stilbestrol is harder, firmer and of a denser (fibrotic) type of structure. The naturally occurring estrogens produce a breast tissue growth having the physical characteristics of normal breast tissue; these normal breast tissue characteristics are not present in stilbestrol-induced mammary growth. Another important point of differentiation observed is that the stilbestrol-induced breast development resolves at a much more retarded rate than the natural estrogen-induced mammary growth.

A dissimilarity of action of stilbestrol and the follicular hormone in the production of fibroids in the guinea pig uterus has been reported by Lipschutz and Vargas,³ who state: "This tumorigenic action of stilbestrol is much greater than that of the natural hormones (estradiol and estrone) when equal quantities are compared. . . . The guinea pig uterus increases beyond the normal weight more rapidly with stilbestrol than with the free natural hormones. This is tentatively explained by an inability of the organism to inactivate stilbestrol so rapidly and effectively as estradiol and estrone."

The initial objective of the therapy in this case was to inhibit the hypersexual state. Under the administration of stilbestrol the penis and testes have diminished to approximately two thirds of the pretherapeutic size. The patient states that there is an absence of libido and that masturbation does not produce an ejaculation of seminal fluid.⁴ A complete report of the sexual aspect of the case will be reported after urinary bioassays and testicular biopsy have been performed. Stilbestrol therapy is being continued.

In view of the foregoing subjective and objective clinical observations, it can be reported that stilbestrol produces mammary tissue development to a stage of advanced gynecomastia in the male and also stimulates the growth of mammary tissue in the female. The physical characteristics of the breast tissue reaction of stilbestrol and the naturally occurring estrogenic substances are markedly dissimilar in that the stilbestrol-induced mammary tissue growth is harder, firmer and denser and its rate of resolution after the discontinuance of therapy is markedly retarded as compared with that resulting from the administration of the naturally occurring estrogenic substances.

CONCLUSION

The administration of 480 mg. of stilbestrol to a man aged 27 produced a marked bilateral gynecomastia, the physical characteristics of which were dissimilar to that observed in males treated with the natural estrogenic substances. This dissimilarity of effect was also observed in female patients.

A marked diminution of sexual function, from a hypersexual state to what is considered a hyposexual state, has been obtained.

It is assumed that the therapeutic effect has resulted directly from depression of the anterior pituitary gonadotropic function and indirectly from inhibition of male hormone production in the testes or primary depression of testicular hormone formation. No clinical evidence of other disturbances in anterior pituitary function has been observed.

The administration of 480 mg. of stilbestrol produced no signs of the toxic effects attributed to stilbestrol.

CHICAGO

Diethylstilbestrol, the synthetic estrogen which has been named stilbestrol for convenience, has aroused widespread interest because of its remarkable effectiveness in replacement therapy.¹ In addition to possessing most or all of the therapeutic properties of the natural estrogens, it has great potency on oral administration, which makes it a convenient substance to use.² However, there has been much concern over the significance of certain side effects which occur in some patients following stilbestrol medication.

Most authors have reported that about 10 to 20 per cent of their stilbestrol-treated patients complained of gastrointestinal distress, principally nausea.³ The reports

dence of liver damage in their stilbestrol-treated patients. Using the bilirubin retention and the hippuric acid excretion tests, they found some indication of decreased liver function by the first method but not by the second.

We report some observations on stilbestrol which, while they do not explain the minor unpleasant reactions which occur in some patients, lead us to believe that the drug is not significantly toxic to the liver.

METHODS AND RESULTS

Our patients were an unselected group of women suffering from the typical menopausal syndrome. In all but a few the menopause was of natural origin. Since the toxicity of a substance has little significance except in relation to its therapeutic dosage, our first work with stilbestrol was an attempt to approximate the latter. Table 1 summarizes our results in a representative group of patients of whom the same ones were treated at different times and after suitable control

periods with stilbestrol⁵ and estradiol respectively. The number of plus signs indicates our comprehensive judgment of the degree of relief obtained in each instance; 4 plus indicates complete relief of all signs and symp-

toms. It was our practice to start stilbestrol treatment with 0.5 mg. daily and to raise this dose to 1.0 mg. daily if complete relief was not obtained with the smaller dose. It may be seen that the oral administration of 0.5 to 1.0 mg. of stilbestrol daily yields somewhat better relief of the menopausal syndrome than does the daily ingestion of 400 oral rat units of estradiol.

In view of the age group in which our patients fell it seemed inadvisable to select one of the more highly sensitive tests of liver function, which would undoubtedly reveal minor degrees of asymptomatic liver damage in many of our patients whether they were treated with stilbestrol or not. We therefore chose the bromsulphalein retention test, which is generally recognized as being sensitive to liver deficiency of clinically significant degrees. As used by us, 5 mg. of the dye per kilogram of body weight is injected intravenously in one arm. One half hour later a blood sample is withdrawn from the opposite arm. The amount of bromsulphalein remaining in the serum at that time is determined colorimetrically. A retention of 15 per cent is considered to be the upper limit of normal.

Table 2 shows a comparison of the results of the bromsulphalein test in 12 menopausal women who had been treated with stilbestrol for various lengths of time, with the results in an equal number of apparently normal, untreated women in the same age group. Only 3 women in the group treated with stilbestrol

and an equal number in the untreated group showed abnormally high bromsulphalein retentions. Nor was there any relationship between the total dose of stilbestrol and the degree of dye retention. It is probable, therefore, that the indicated liver damage was present in the menopausal women before the treatment was instituted.

However, the somewhat greater degree of dye retention in the entire group of menopausal women as compared to the control women suggested the possibility that stilbestrol might have some injurious effect on livers which were already suffering from some slight damage. Bromsulphalein retention tests were therefore done on another group of menopausal women, both before and after they had received stilbestrol. It will be noted in table 3 that in not a single instance was the bromsulphalein retention greater after stilbestrol treatment than before it. In fact, the reverse was true in 4 out of the 8 cases so observed. This seems especially significant in view of the fact that patients 6, 7 and 8 manifested abnormally high degrees of dye retention before treatment and were purposely given 5 to 10 times our usual therapeutic dose of stilbestrol.

At this point in our work it was quite apparent that, as judged by the bromsulphalein retention test, therapeutic doses of stilbestrol did not cause liver damage, nor did they aggravate the preexisting mild deficiencies

present in some menopausal women. However, none of the women available for this study had manifested any significant clinical signs or symptoms of liver damage. It therefore seemed important to test the possible toxicity of stilbestrol in at least 1 patient (whether menopausal or not) with frank and unquestionable liver disease. The opportunity of a test soon presented itself in J. L., a white man aged 38 who was convalescing from an attack of acute hepatitis.

Before detailing the experimental procedure with the patient just mentioned it is necessary to outline certain animal experiments which, in addition to the observations already presented, had given us sufficient assurance that he would come to no harm.

* 1.75 Gm. of dextrose per kilogram of body weight, injected intravenously in 30 per cent solution.

1. Twelve adult female rats were placed on our usual Purina Fox Chow diet supplemented with 10 per cent powdered milk. In this diet was mixed an amount of stilbestrol which, from the quantities of food eaten each day, resulted in a stilbestrol intake of about 7 mg. per rat daily. At the end of fourteen days the amount of stilbestrol in the diet was doubled, and the new amount was continued for another period of fourteen days. This dose of stilbestrol, when considered in terms of the body weight and life span of the rat, corresponds to a relatively enormous dose over a period of several years in man. Nevertheless the animals were grossly normal when killed for postmortem examinations. The livers and kidneys failed to show any gross or microscopic pathologic conditions, except for the occasional slight, cloudy swelling which frequently be observed in the tissues of normal rats.

2. To ascertain the cell structure of the liver and kidneys of stilbestrol on the absence of toxic effect on hepatic function, was paralleled by an experiment on a dog. This animal ingested a similar experiment was done on a dog. Table 4 gives the results of our estimations of the icterus index, serum cholesterol, dextrose tolerance and bromsulphalein retention, both before and after the stilbestrol treatment. There was no evidence of any functional impairment.

Patient J. L. entered the hospital complaining of nausea, vomiting, jaundice, pruritus and clay-colored stools, of three weeks' duration. On physical examination there was slight tenderness in the right upper quadrant of the abdomen. The liver was palpable 4 cm. below the costal margin in the right midclavicular line; the lower edge was smooth and firm. A diagnosis of acute catarrhal jaundice with hepatitis was made. The icterus index at the height of the patient's illness had reached a level of 80, his cholesterol-cholesterol ester ratio was reduced to 27 per cent. He had returned to normal and his cholesterol-cholesterol ester ratio was up to 59 per cent. His bromsulphalein

retention at this time was 60 per cent. His symptoms were entirely gone.

The daily administration of 10 mg. of stilbestrol orally was now begun and continued for three weeks. During this period, despite the intake of 210 mg. of the drug, the patient continued to show clinical improvement. By the end of the period the icterus index was still normal, the cholesterol-cholesterol ester ratio had become normal (78 per cent) and the bromsulphalein retention had dropped to 20 per cent.

SUMMARY

With the therapeutic doses (1 mg. daily) and the particular product which we used there was no evidence of any toxic action of stilbestrol on the livers of the menopausal women whom we treated. This was true even with doses of 5 to 10 mg. daily and in women who exhibited some liver dysfunction to begin with as judged by the bromsulphalein retention test. Furthermore, relatively huge doses of stilbestrol in rats and a dog did not give rise to gross or cellular pathologic conditions of liver or kidneys or to liver damage as judged by various criteria of hepatic function. Finally, a patient with indubitable liver damage who was recovering from an attack of acute hepatitis was able to take ten times our usual therapeutic dose of stilbestrol for a period of three weeks without the slightest evidence that his convalescence had been impeded.

It must be concluded that in our experience stilbestrol is not significantly toxic to the liver. We are unable to explain the gastrointestinal distress which follows the use of stilbestrol in some patients. Until this is explained it seems wise to discontinue the administration of stilbestrol in any patient who begins to complain of nausea or other side effects. Meanwhile, there seems to be little reason for withholding the use of a potent and convenient estrogen in such patients as do not experience these side effects.

CLINICAL STUDIES ON STILBESTROL

EMMERICH VON HAAM, M.D.

AND
R. H. SCHOENE, M.D.
COLUMBUS, OHIO

In a previous paper¹ we have reported our results on animal experiments concerning the toxicity and activity of stilbestrol. We found that the close similarity of the action of natural and synthetic estrogenic substances on the female sex organs and the pituitary gland of immature, mature and castrated animals could be confirmed. Some evidence of toxicity could be observed in our animals after we administered doses of stilbestrol as low as 0.1 mg. three times a week, although the changes at higher dose levels were not as drastic and alarming as those reported by Loesser.² Clinically the drug has been used by numerous investigators of the Continent and recently also in the United States for

the treatment of various ovarian disorders. While the reports on the activity of the drug in the majority of cases are very encouraging, considerable discrepancy exists with regard to the untoward symptoms observed in some patients after its administration. It is the latter fact which up to the present time has caused the American Medical Association to withhold official recognition of stilbestrol. In reporting our own clinical experiences with this drug we shall discuss separately our findings concerning its efficacy together with the pertinent data from the literature and our clinical investigations concerning the toxicity of this drug in human beings.

ESTROGENIC PROPERTIES OF STILBESTROL

First tested on a more extensive scale by Winterton and MacGregor,³ stilbestrol has proved highly effective in controlling symptoms of menopause. Three patients with kraurosis vulvae were markedly improved. Ten of 11 patients with secondary amenorrhea started to bleed after sufficient therapy. Tüscher⁴ treated successfully postpartum amenorrhea with 1.5 mg. once a week. If given to normal women it produced sensitive swelling of the breasts and clitoris with increased libido. Kellar and Sutherland⁵ used it for successful control of menopause, senile vaginitis, leukoplakia and secon-

dary abortion. Guldberg⁶ was able to produce a normal progestational endometrium by giving a 22 year old castrate woman with intact uterus 20 mg. of stilbestrol

for eighteen days followed by 30 rabbit units of synthetic progesterone for six days. Evelbauer⁷ reported success of treatment in 50 climacteric patients with comparatively small doses. He did not have any success treating uterine hypoplasia and amenorrhea and recommended the natural estrogen for patients with these conditions. Buschbeck and Hausknecht⁸ reported

success in cases of amenorrhea with total doses of as little as 20 mg., given in 5 mg. doses. A similar experience was reported by Heisler.⁹ Engelhart¹⁰ induced "menstruation" in castrate women. Brühl¹¹ treated successfully endometrial hemorrhages with 2 to 3 mg. of stilbestrol. He also had success in the treatment of dysmenorrhea, dyspareunia and lack of libido. According to Lindemann¹² the estrus produced by diethylstilbestrol dipropionate lasted twice as long as the one produced by estradiol benzoate. Varangot¹³ found stilbestrol three times as effective as crystalline estrone if given by injection and six times as active as estradiol benzoate when given by mouth. In 18 cases improvement was achieved by daily doses of 0.3 mg. The danger of overdosage was stressed by Ehrhardt, Kramann and Schäfer.¹⁴ They found 12 mg. of stilbestrol

sufficient to produce a normal proliferating endometrium and recommended 0.5 to 1 mg. as single doses and 2 to 5 mg. as a weekly dose for the treatment of the menopause. Bishop, Boycott and Zuckerman¹⁵ produced withdrawal bleeding in 8 patients with amenorrhea and rhythmic hemorrhages in 2. Biopsy of the breast after administration of 280 mg. by mouth showed epithelial proliferation with no increased secretory activity. In their summary Bishop and his co-workers emphasized the close resemblance of the effect of stilbestrol to that of natural estrogen. Both produce withdrawal bleeding, a proliferative type of endometrium, growth of the hypoplastic uterus, relief of the menopausal syndrome, restoration of the vaginal smear into the estrous type, proliferation and activation of the mammary glands with painful swelling of the breasts and relief of dysmenorrheic pains. Cessation of lactation after administration of stilbestrol in cases of stillbirth was reported by Tietze¹⁶ and Lindemann.¹² Peel¹⁷ showed that stilbestrol had little value in inducing labor although it

plasia the therapeutic effect of stilbestrol was identical with the one produced by the natural estrogen. MacBryde, Freedman, Loeffel and Allen²⁰ studied 37 cases of various types of ovarian deficiency. They were able to produce withdrawal bleeding and mammary growth at will. Implantation of pellets weighing 100 mg. each to 6 castrated patients produced an estrous type of vaginal smear within two days and endometrial proliferation within seven days. The menopausal symptoms were greatly relieved as long as the pellets remained in place. The average daily absorption could be determined as ranging from 0.127 to 0.250 mg. Karnaky²¹ treated 189 patients with menstrual disorders. He found stilbestrol as effective as natural estrogens. Geist and Salmon²² used the drug in 38 menopausal women in doses of 1 to 5 mg. three times a week or in tablets of 3 to 5 mg. daily. The women showed a positive vaginal smear as early as four days after treatment and a complete control of hot flashes. However, headaches and nervousness were not strikingly relieved.

was definitely advantageous in increasing the tone and uterine contractions.

In the United States six reports have appeared up to the time this report was written on clinical trials with stilbestrol. Shorr, Robinson and Papanicolaou¹⁸ studied its effect on forty-four women, many of whom had been treated previously with natural estrogens, and confirmed its powerful estrogenic action. Only 2 of the 44 patients failed to show an estrous type of vaginal smear. They found that 1 mg. of stilbestrol was equivalent to 1.7 mg. of estrone and emphasized the great advantages of oral administration. Kurzrok and his co-workers¹⁹ studied 40 cases of various gynecologic disorders. Fifteen menopausal patients obtained symptomatic relief, sometimes as early as twelve hours after the initial treatment. In the other 25 cases of amenorrhea, oligomenorrhea, dysmenorrhea and uterine hypoplasia the therapeutic effect of stilbestrol was identical with the one produced by the natural estrogen.

In our clinical studies a series of 125 patients with surgical and natural menopause were treated from two weeks to six months with doses ranging up to 60 mg. (table 1). Series A is composed of patients studied at the endocrine clinic of the University Hospital; series B comprises patients treated in private practice. We thought a separation of our material into these two groups might be of interest since a marked difference existed between these patients with respect to the presentation of their symptoms and of any subsequent changes. The stilbestrol was administered in the majority of cases by oral therapy in daily doses of 0.2 to 0.5 mg. This was found to be the most effective type of treatment as it produced the least amount of disagreeable symptoms. Parenteral therapy was usually used in doses of 1 mg. twice a week. The duration of treatment extended in the majority of cases from one to three months. Only 2 patients had therapy for one year.

Our results showed a considerable difference between the patients of series A and B, justifying the division

of our material. While 71 per cent of the patients of series B reported complete relief of all symptoms, only 30 per cent of our charity patients were content with the therapy. Poor or adverse results were obtained in only 13 per cent of the privately treated patients, while it was present in 32 per cent of the patients treated at the clinic. The reason for this marked discrepancy is probably a less careful selection of suitable material in series A, since the mental capacity of our patients often makes proper recognition of the menopausal syndrome difficult. Economic factors and social problems may also have some part in the differences in our therapeutic results. Eighty-one patients of both series had had previous experience with other estrogenic drugs. Thirty-two per cent of series A and 42 per cent of series B reported better results after stilbestrol than

as early or as consistently, and we wish to withhold further comment on this until more studies have been accomplished. Excessive stimulation of the sexual organs was found in a sufficient number to be worth mentioning. The most alarming symptom was the appearance of vaginal bleeding, which was noticed in 8 cases. It occurred in patients who at the time of treatment were one and a half years past the last men-

with any other estrogenic substance tried. A total of 25 per cent reported an equal result, while 28 per cent reported less success.

As objective signs of improvement we have taken the decrease or disappearance of the gonadotropic substance in the urine of pregnancy and the appearance of estrus as evidenced by the vaginal smear method and the determination of the urinary estrogens. From table 2 we learn that 64 per cent of the patients treated at least for one month with stilbestrol showed no significant amount of gonadotropic substance in the urine as contrasted to only 23 per cent of the untreated control group, while over half of the treated patients showed a large amount of estrogenic substances. The vaginal smear changed in almost all instances within the first week of treatment from a menopausal to an estrogenic type. Changes in the endometrium were not observed

strual period and lasted up to twenty-one days. Curettage revealed a moderate or marked proliferation of the endometrium without evidence of the secretory phase. Vaginal discharge was observed in 7 cases. Mammary symptoms consisting of painful fullness of the breast, and some nodular swellings were present in 5 cases. Increased sexual stimulation was present in 3 cases. In those climacteric women who were still menstruating while under treatment, stilbestrol therapy affected the menstruation. Three menstrual periods were delayed, and one stopped; in 11 cases cramps accompanying the period were increased or appeared, and at the same time the patient complained of headache.

Chart 2.—Gastric analysis after alcohol test meal in 4 patients treated with small doses of stilbestrol.

We may say that stilbestrol has proved to us, in the doses administered orally to patients, a powerful estrogenic substance. It is our opinion that most of the doses recommended so far in the literature are excessive and that smaller doses should be used. We believe also that its continuous administration is unnecessary and that it should best be spaced at regular intervals. By using discretion in its administration an excessive stimulation of the sexual organs can well be avoided.

although this stimulation seemed in no way harmful and in no way different from the effects produced by excessive doses of natural estrogen. We feel, furthermore, that the more intelligent type of patient, who shows better cooperation with the physician, will receive greater advantages from the treatment.

CLINICAL STUDIES OF TOXICITY

Already the earliest investigators of stilbestrol have observed that its oral administration caused a number of untoward symptoms in patients which were sometimes so pronounced that the administration of the drug had to be discontinued. Reports of the incidence of these so-called toxic effects vary and are probably dependent a great deal on the type of patients and the carefulness of clinical observation. In the brief tabulation of the toxic symptoms as cited so far in the literature we observe a remarkable variation of incidence reported by the various authors (table 3). The symptomatology of stilbestrol has been best studied by Shorr, Robinson and Papanicolaou¹⁸ and by Varangot.¹³ Shorr and his associates found lassitude the most prominent symptom. They observed in their series 6 patients with vertigo, 8 with erythema, 1 with toxic psychosis, 1 with paresthesia and 1 patient afflicted with unquenchable thirst. As a rule these symptoms persisted, and a second course of treatment was tolerated as poorly as the first. Toxic reactions were also obtained two to three hours after injection of stilbestrol. Their appearance could not be correlated with any critical level, and Shorr and his associates postulated that all indications pointed to an injury to the central nervous system as their cause. Varangot distinguished between early and late toxic symptoms after administration of stilbestrol.

after meals with nausea, vomiting and vertigo. Loss of appetite and general malaise were present, and the patient urgently insisted on discontinuance of the therapy.

Available laboratory reports have so far failed to show any tangible evidence of toxicity in human beings. The

Chart 4.—Urinary excretion of stilbestrol, in 3 patients after injection of 1 mg. to 10 pounds (4.5 Kg.) of body weight. I. M. U., infantile mouse uterus.

tests involved include red blood cell counts; leukocyte counts; hemoglobin determinations; urinalyses; serum protein determinations; icterus index and van den Bergh reactions; bromsulphalein, galactose and hippuric acid tests, and prothrombin determinations (MacBryde and his co-workers, Buxton and Engle²³ and Shorr and his co-workers). No evidence of allergic or urticarial phenomena was obtained.

In section 5 of our clinical summary (table 1) the so-called toxic symptoms encountered during treatment with stilbestrol are analyzed. A total of 52 patients, or approximately 42 per cent, complained of some untoward symptoms during treatment. In the majority of cases nausea and vomiting were the principal and only cause of complaint. Headaches and dizziness rated second in importance. One case of psychotic excitement and 2 cases of severe diarrhea occurred during stilbestrol therapy. One exceedingly sensitive patient had a severe local reaction consisting of vaginal discharge, cystitis, backache, itching of the vulva and marked stimulation of the breast on a total dose of 3 mg. given orally in 0.5 mg. doses for six days. In another patient there developed in the course of treatment a galactocoele of the breast.

In the clinical evaluation of the aforementioned symptoms we may state that although they were decidedly disagreeable they appeared not in any way seriously harmful and disappeared in all instances as soon as treatment with stilbestrol was discontinued. They could be observed either immediately after the first administration of the drug or shortly thereafter and were likely to develop more frequently after oral administration, although parenteral administration occasionally produced them. Reduction in the dose usually decreased the severity of these symptoms sufficiently so that the patient could carry on with the treatment. Only in 9 cases were we forced to discontinue the therapy. Our attempt to avoid the gastrointestinal symptoms by administering the drug in enteric coated tablets has met with failure so far; 5 out of the 6 patients treated in this manner became nauseated.

A series of clinical investigations was undertaken with the purpose of discovering definite evidence of toxicity

Chart 3.—Gastric analysis after alcohol test meal in 4 patients treated with nauseating doses of stilbestrol.

Usually the patient was taken ill on the second day with feelings of nausea and vomiting. Even if the administration of stilbestrol was immediately stopped, the complaints persisted for one to two days. Continuation of treatment made the complaints more accentuated. The late symptoms, which set in after two months of treatment, consisted of burning gastric pain occurring

23. Buxton, C. L., and Engle, E. T.: Effects of the Therapeutic Use of Diethylstilbestrol, J. A. M. A. 113: 2318 (Dec. 23) 1939.

of the drug in the doses administered to human beings. Our study was conducted on men and women patients who were admitted to the hospital and treated with doses of stilbestrol. Repeated, and in one instance daily, blood counts were done with determinations of all formed elements in the blood. Although occasionally an abnormally low value was obtained, such as 152,000 for thrombocytes or 3,500,000 for red blood cells, in no instance could any evidence of a permanent injury to the blood be obtained (table 4). A specimen of bone marrow which we took for biopsy from a patient with a low red blood cell count showed hyperplasia of the erythropoietic elements and a small increase in the monocytes and eosinophil myelocytes. The blood sugar curves determined on 3 patients who obtained one single large dose of stilbestrol showed no consistent changes in the dextrose tolerance (fig. 1).

Because of the predominance of gastrointestinal symptoms gastric analysis was performed before and after administration of stilbestrol. In one group of patients small doses which did not produce any nausea were given over three days. Although the acid value while the patient was fasting was lower than before administration of the drug, the acidity rose to a higher peak after an alcohol test meal (fig. 2). We then administered to 4 patients doses of 10 mg. daily, which produced severe nausea with vomiting. The analysis of the gastric secretion showed irregular curves, which, however, inclined more to the side of hypoacidity (fig. 3). With reference to our animal experiments in which we definitely observed mucosal atrophy of the stomach after toxic doses, we suggest that small doses of stilbestrol may exert an irritating effect, while large doses have a depressing effect on the gastric secretion. It is the latter factor which probably is responsible for the nausea.

All other laboratory tests which were done on the patients before and after treatment with stilbestrol failed to show any evidence of organic injury (table 5). The liver function, as determined by the icterus index, the prothrombin level of the blood, the Weltmann coagulation band, the serum bilirubin and the bromsulphalein test, was normal in all our patients. The kidney function, as determined by the blood urea nitrogen and the blood creatinine, was not impaired. The urine of the patients showed in no instance albumin or casts. The blood chlorides (Selye²⁴) were not changed.

In order to determine the fate of the injected stilbestrol, the excretion of the substance was determined quantitatively in the urine and feces of 3 patients who received one large dose of the drug (10 to 15 mg.). Figure 4 shows the daily excretion in the urine as measured by the equivalents of twenty-four hour urine extracts which were necessary to produce 100 per cent increase of the infantile mouse uterus.²⁵ The excretion of the drug in the urine begins immediately after its administration, reaches its highest levels on the third to the fifth day and decreases rapidly to a small amount, which then can be found in the urine for some time. We carried on the determinations for sixteen to twenty days, until even the last trace of the substance had disappeared. The feces during this period gave a strong estrogenic reaction, and we must assume that a considerable portion of the ingested stilbestrol is excreted with the feces. An approximate calculation of the

excreted amount would suggest that from 10 to 30 per cent of the ingested stilbestrol was excreted within the first ten days after its administration.

SUMMARY AND CONCLUSIONS

One hundred and twenty-five patients with surgical and natural menopause were treated from two weeks to six months with doses ranging up to 60 mg. of stilbestrol. In 75 per cent of the cases excellent or good results were obtained, with 39 per cent of the patients reporting better response to this therapy than to any other estrogenic substance used previously. In 42 per cent of the patients some untoward symptoms appeared during the therapy. These, however, could be controlled in the majority of cases by reducing the dose, and the treatment had to be discontinued in only 9 cases.

Laboratory investigation of the function of the parenchymatous organs and of the erythropoietic system did not reveal any evidence of organic injury. A gastric analysis showed a slightly decreased response of the mucosa to the alcohol test meal after the administration of nauseating doses of the drug. Ten to 30 per cent of the ingested stilbestrol was excreted in the urine and feces during the first ten days following its administration.

We feel that because of the ease of administration and the great economic advantages stilbestrol has a definite place in the treatment of the menopause provided that small doses are used and that the therapy is not continued over too long a time.

Clinical Notes, Suggestions and New Instruments

DERMATITIS DUE TO A FACE POWDER CONVEYOR

LESTER HOLLANDER, M.D., PITTSBURGH

Mrs. R. H., aged 49, an American housewife, referred to me by Dr. Charles E. Hays of Johnstown, Pa., on May 7, 1940, presented a sharply defined, vesiculo-erythematous eruption which involved the nose, the upper lip and the adjacent portion of the right lower eyelid. The tip of the nose and the central furrow of the upper lip were thickened and cracked, these being the areas of the most marked involvement. The eruption was of approximately four months' duration and it was exceedingly itchy.

It was evidently due to some sensitizing contact substance, but neither the history of the onset and course nor any variability in the intensity of the subjective symptoms gave me any clue except that the substance had something to do with the face and especially with the nose.

Accordingly the patient was instructed to stop the use of her cosmetics, soap, handkerchiefs and cleansing tissues for a period of two weeks. At the expiration of that period she returned; her face was practically clear, indicating that I was on the right track. Patch tests were now done with all the interdicted substances and articles, including face powder, rouge, lipstick, nail lacquer, cleansing and tissue creams, perfume, wave set, soap and cleansing tissue. These were negative at the end of forty-eight hours and also at the end of one week.

Because of the clinical improvement after the discontinuance of her cosmetics and soap she was instructed to return to the use of these singly, one week apart, so as to ascertain the cause as the eruption would reappear.

On August 7 she returned with a marked recurrence of the eruption. I was unable to trace back the irritant because, after being free from the eruption for a few weeks, the patient returned to her regular cosmetic and cleansing routine.

I decided to retest her to her cosmetics. In obtaining the various samples for the patch tests her face powder was pro-

24. Selye, Hans: On the Toxicity of Oestrogens with Special Reference to Diethylstilbestrol, *Canad. M. A. J.* 41: 48, 1939.

25. von Haam, Emmerich: The Direct and Indirect Determinations of Estrogenic and Gonadotropic Hormones, *Am. J. Clin. Path.* 10: 205, 1940.

duced from a rubber sponge powder puff. It was rounded and biscuit-like with a central pocket reached through a lateral slit. The porous quality of the rubber permitted the escape of the face powder when the skin was patted with the puff. She bought this puff shortly before the original onset of this eruption and used the puff to powder her nose only when she was away from her home. The outline of the eruption was confined to the area of its use.

Patch tests of the puff, with and without the face powder, were strongly positive in twenty-four hours, while the patch test of the face powder alone was again negative.

This case is of interest because a dermatitis was produced by a conveyor of a cosmetic, a rubber sponge powder puff, and there is no mention of such an occurrence in the literature. 631 Jenkins Building.

PRENATAL DIAGNOSIS OF COMPLETE CONGENITAL HEART BLOCK

Clyde J. Geiger, M.D., and Laurence E. Hines, M.D.
Chicago

About seventy cases of congenital heart block have been recorded. Yater's¹ review of cases prior to 1929 included only thirty cases of well established block. The criteria used by him and in subsequent reviews were auriculoventricular dissociation proved by a graphic method in a relatively young person, development of bradycardia at a fairly early age, and absence of a history of infection which might cause heart block. In 1934 Hays² collected twelve additional cases. Since then about twenty-six additional cases have been reported. The age at which the diagnosis of heart block has been made varies from birth up to 20 years. Only five cases including our case have been diagnosed before birth. Yater,¹ Witt,³ Heubner⁴ and Ottow⁵ have made a prenatal diagnosis of complete heart

REPORT OF CASE

Mrs. F. H., a white primipara aged 30, a patient of Dr. E. W. Mosley, was admitted to the obstetric service at St. Joseph Hospital Dec. 2, 1939. Her antepartum course had been uneventful. She had had no serious illnesses or operations in the past. She was well nourished and presented the usual manifestations

Leads 1 and 2 of electrocardiogram.

of pregnancy at full term, blood pressure 116 systolic, 86 diastolic, a negative Wassermann reaction, a normal blood count and normal urine. At the time of admission the bag of waters was intact, the head was not engaged, labor pains were mild and irregular and the fetal heart tones were 136 per minute. Two hours after admission the labor pains were still mild and irregular. No engagement of the head had taken place but the fetal heart tones had dropped to 64 per minute. The slow fetal heart rate varying from 58 to 64 per minute persisted until the time of delivery, which occurred nineteen hours after admission. At first the sharp drop in fetal heart rate caused suspicion of impending fetal asphyxia. However, the persistence of regular forceful beats between pains was not characteristic of asphyxia and a diagnosis of heart block was considered and labor was allowed to proceed normally. A healthy female infant weighing 3,180 Gm. delivered spontaneously forty-eight

Review of Previously Reported Cases of Prenatal Diagnosis of Heart Block

Author	Sex	Slowest Fetal Heart Rate	Slowest Rate After Birth	Time of Prenatal Diagnosis	Malformations	Heart Enlargement	Proof of Block	Cyanosis	Duration of Life	Other Observations

minutes after the beginning of the second stage of labor. The baby and mother were discharged in apparent good health nine days after the birth. The infant was well nourished and healthy. There was no cyanosis, no enlargement of the heart, no murmurs and no abnormal accentuations. Repeated electrocardiograms, one of which is shown in the illustration, revealed complete heart block with an auricular rate of 120 and a ventricular rate of 60, right axis deviation and flat T waves in all leads. A roentgenogram of the chest revealed a heart and aorta of normal size and contour. The retrocardiac space was clear. The lung fields were well aerated. April 1, 1940, the baby was in good health except for the heart block, which a recent electrocardiogram showed was still present.

COMMENT

Prenatal diagnosis of complete heart block has been reported only five times. The accompanying table includes the important information in the five reported cases. The time of diagnosis prior to birth varied from seventeen hours to two months. In all instances the diagnosis was made by detection of an unusually slow regular fetal heart rate (32 to 80). All

diagnoses were confirmed by electrocardiograms, which showed complete auriculoventricular dissociation. In our case a differentiation between asphyxia and heart block was necessary because the onset of block occurred during the course of labor. Asphyxia as the cause of fetal bradycardia was ruled out in this case because the rate was constant and the strength and regularity were not influenced by uterine contractions.

Necropsies on patients with congenital heart block usually have shown congenital malformations. Two patients of this series died and autopsies revealed congenital anomalies in each. Both fatal cases also showed typical clinical evidence of congenital defects, as evidenced by cyanosis, murmurs and enlargement. However, the other three, all living, showed no clinical evidence of congenital defects, and it is possible that other transient lesions of the bundle of His may cause the block. Hemorrhage or toxic or inflammatory lesions might reasonably produce a temporary defect. This is suggested by the termination of the block in Heubner's case and also by the termination of partial block in other cases. The absence of toxemia in the mother and the development of the block early in labor lend no support to hemorrhage or infection as an etiologic factor in our case.

The presence of cyanosis and of other signs of congenital heart defects in patients with complete congenital heart block points to an early unfavorable prognosis. If the block is not associated with clinical evidence of congenital defects, the health of the child may be unimpaired and the prognosis less serious.

SUMMARY

A case of complete heart block was diagnosed before birth. A sudden slowing of the fetal heart rate which occurred between seventeen and nineteen hours before birth points to the onset of the abnormal mechanism at a specific time. The sudden onset of the heart block demanded a differential diagnosis between heart block and intra-uterine asphyxia. No anatomic abnormalities in the heart have been demonstrated, and the child is alive and healthy at 5 months of age.

COLLES FRACTURE SPLINT

VERNON L. HART, M.D., MINNEAPOLIS

Numerous types of splints have been described for maintaining the reduction of a Colles fracture of the wrist. I have used many of them—nonpadded plaster, wooden, sugar tong plaster, anterior and posterior plaster molds, Schede's splint and commercial form-fit splints—but now regularly use the plaster splint to be described because it is easily applied, comfortable and efficient and it prevents complications. The two most distressing complications not infrequently observed are recur-

Fig. 1.—Ulnar view of plaster splint showing strip of plaster removed from the ulnar side of the entire splint, plaster removed from the ulnar styloid prominence, and complete flexion of interphalangeal and metacarpophalangeal joints.

rence of radial deviation deformity of the distal fragment of the radius and hand and loss of function of the fingers and thumb because of adhesions and contractures of tendon sheaths and tendons. The plaster splint is applied over stockinet. Not more than two or three 4 inch plaster of paris rolls are used.

No padding is used except for a small piece of felt over the radial or thumb site of the second metacarpal bone. Pressure at this point (fig. 2) is essential in order to maintain reduction of the distal radial fragment and hand in ulnar deviation. The original deformity is radial deviation of the distal radial fragment and hand and this often recurs after perfect reduction if immobilized in splints which do not maintain ulnar deviation.

After the plaster has hardened, a strip of plaster about one-half inch in width is removed from the ulnar side of the splint (fig. 1). This permits the splint to expand and accommodate the swelling which results from hemorrhage. Excessive swelling with edema will not occur if the fractured extremity is continuously elevated during the first several days after the injury.

A niche of plaster also is removed over the prominence of the ulnar styloid process to prevent pressure necrosis and pain.

The plaster is cut away so that complete flexion will be possible at the interphalangeal and metacarpophalangeal joints of the fingers (fig. 1). The second metacarpophalangeal joint will be slightly limited in flexion because of the extension of plaster along the thumb side of the second metacarpal.

Plaster is next cut away to permit complete range of all motions of the thumb. The window at the thumb is extended proximally to remove plaster pressure and prevent pressure necrosis and pain at the base of the thumb or first carpometacarpal area (figs. 2 and 3). The plaster extends over the extensor surface of the metacarpals to the knuckles to maintain the position of the reduction in palmar flexion (fig. 2).

If x-ray studies demonstrate good reduction, the splint should be worn continually from four to six weeks. The patient is instructed to flex and extend all interphalangeal and meta-

Fig. 2.—Extensor view of splint which demonstrates the plaster pressure over the radial side of the second metacarpal bone to maintain reduction in ulnar deviation, the thumb window, plaster removed from ulnar styloid, and plaster extension to knuckles.

Fig. 3.—Radial view of splint which shows the thumb window and extension of plaster over the radial side of the second metacarpal bone.

carpophalangeal joints of the thumb and fingers completely and actively. Also the patient is instructed to rotate the thumb by touching the tip of the thumb to the end of each individual finger and to abduct and adduct the thumb and fingers. Supination and pronation of the forearm should be encouraged. The elbow and shoulder joints should be moved actively through the normal range of all motions. Besides these active subjective exercises the patient should be encouraged to perform active objective exercises by using the extremity for such activities as eating, dressing and combing the hair. Many patients may even return to their normal occupation after several days.

Massage, light treatments and passive exercises should have no place in the therapeutic program of a fresh Colles fracture.

GLANDULAR PHYSIOLOGY AND
THERAPYLACTOGENIC AND MAMMOGENIC
HORMONES

OSCAR RIDDLE, Ph.D., LL.D.

COLD SPRING HARBOR, N. Y.

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in these articles are those of the authors and not the official views of the Council.—Ed.

Investigations of the past twelve years provide much new information concerning the regulation of growth and of secretion in the mammary glands. Both growth and secretion are controlled mainly by hormones, but quite different hormones are involved in these two wholly distinct sets of processes. The anterior lobe of the pituitary exercises a direct control (through its lactogenic hormone, prolactin) over milk secretion; in addition it exercises an indirect control (through estrogen, progesterone and possibly other sterols) and perhaps also a direct control (through a mammogenic pituitary hormone) over the development and growth of the mammary glands.

THE LACTOGENIC HORMONE

The Lactogenic Response.—Stricker and Grüter demonstrated in 1928-1929 that a factor or combination of factors directly essential to lactation is produced by the anterior lobe of the pituitary. Their results were confirmed first by Corner in 1930 and thereafter extended to various species by Nelson and Pfiffner, Turner and Gardner, Asdell and others. Indeed both mammary proliferation and lactation were observed to follow the administration of crude pituitary extracts in females with intact ovaries by Parkes in 1929 (rabbits), by Putnam, Benedict and Teel (bitches) and by Evans and Simpson (rats), but this effect either was or could then be attributed to pituitary influence on hormone production in the ovary. A related response, the enlargement of the crop sacs of pigeons with formation of "crop milk," was reported in 1931 by Riddle and Braucher. All these results were obtained with simple glandular extracts—mixtures of various pituitary products—and provided no indication of the identity of the hormone or hormones that excited this response.

Isolation and Identification of the Hormone.—The individuality of the hormone that excites lactation was established in 1932-1933 through its isolation and study by Riddle, Bates and Dykshorn,¹ who definitely associated it with lactogenic and crop-stimulating functions and called it prolactin. Confirmation of its individuality and lactogenic function was soon supplied by Catchpole and Lyons² and Lyons and other associates,³ who called the hormone mammatropin, and by Gardner

and Turner,⁴ who also fully described the mammary changes accompanying its lactogenic action in the rabbit. Gardner and Turner called this hormone galactin.

Occurrence.—The hormone is probably present in the hypophyses of all vertebrates but is more plentiful in some species and at certain stages of the life cycle than others. Beef and sheep glands usually yield 30 to 40 international units per gram of fresh tissue, while pork glands contain much less.⁵ Pituitaries of fetal calves were once reported⁶ to contain much more prolactin (78 + units) than the glands of adult or pregnant cows (38-44 units), but a later report⁷ stated these values in essentially the reverse order. In the study represented in the latter report a higher concentration of hormone was found in glands from dairy cattle than in those from beef cattle, and in both studies a somewhat higher concentration was found in glands from pregnant (or lactating) cows than in those of heifers. There is evidence that prolactin is formed in the eosinophilic cells⁸ and that administration of estrogen increases the amount of it (stored?) in the rat gland.⁹ Small amounts have been found repeatedly in postpartum human urine (also in urine of normal men and in that of infants during the first week) since this was first reported by Lyons and Page,¹⁰ who stated that the amount excreted daily is equal to that found in one beef pituitary. It is alleged that two peaks of excretion occur within the normal cycle of the female sex: during menstruation and during ovulation.¹¹ Positive tests were reported for human serum¹² and for young (not for mature) placentas¹³ and notable quantities from cystic human breasts.¹⁴ Hoffmann¹⁵ found less than the expected amounts of prolactin in the urine of seven of eight parturient women whose secretion of milk was subnormal. Rabald and Voss¹⁶ reported recovery of a prolactin-like substance from the livers of healthy cattle and hogs but not from horse liver.

Preparation and Assay.—Currently used methods of preparing¹⁷ prolactin from pituitary tissue involve its initial extraction in acid or alkaline medium (aqueous or 60 per cent alcohol [ethyl alcohol], or acid acetone), its isoelectric precipitation in an aqueous medium and repeated washing of this precipitate. Comparisons of the various methods are available.¹⁸ Current methods of assaying prolactin were surveyed by McShan and Turner,¹⁹ Bergman and Turner,²⁰ and Bates;²¹ crop sacs of

pigeons (macro and micro tests available) or of lactation in pseudopregnant rabbits. The micro test in pigeons is said to be sensitive to 0.01 microgram of lactogenic hormone.²²

For assay of this hormone in urine (or serum) Lyons²² now injects unconcentrated urine intradermally (micro test) over the crop sacs of pigeons 1 month old. Four daily injections (0.05 to 0.5 cc.) are made at five sites on each crop gland (feathers removed), with necropsy twenty-four hours after the last injection. After stripping away the muscle and the inflammatory exudate which always results from the toxic substances in the urine and which masks minimal reactions, the crop wall is inspected against good light for stimulation at the sites of injection. By using varying quantities on a few birds, a standard or minimal effective dose of the urine (preserved with hexylresorcinol) is determined.

Four quite different macro units ("pigeon units") now confuse the literature, but a practical solution is at hand. A standard preparation of the lactogenic (crop gland-stimulating) substance—to be distributed on behalf of the League of Nations Health Organization—is available from the National Institute for Medical Research, Hampstead, London, England. Samples made in different laboratories were combined to form this standard preparation, and it was decided that "agreement shall be reached among the members of the Conference as to the activity of the standard preparation in 'Riddle-Bates units' per milligramme, and that the international unit shall be thus defined in terms of the standard preparation."²³

Properties.—Prolactin is insoluble in all fat solvents. It is soluble in water except in the isoelectric region pH 5-6 and in strongly acid solution, < 0.5 . When made acid to the isoelectric point, the extract containing prolactin is precipitated by the usual protein precipitants—e. g., by tannic, phosphotungstic, flavianic and trichloroacetic acids and by trinitrophenol. It may be salted out with sodium (or ammonium) sulfate or sodium chloride, the amount required depending on the pH . It is also precipitated by basic salts of heavy metals at or near pH 7.²⁴ It is rapidly inactivated by trypsin²⁵ and pepsin.²⁶ Salt-free solutions at pH 8 withstand boiling for one hour with little loss; under other conditions the prolactin may be rapidly destroyed.²⁷ A crystalline protein with fairly high lactogenic activity was extensively studied by White, Catchpole and Long²⁸ and found to have the following elemental composition in percentage: carbon 51.11, hydrogen 6.76, nitrogen 14.38, sulfur 1.77, phosphorus 0. In their better preparations of prolactin Bates and Riddle²⁹ found roughly 2 per cent each of tyrosine, cystine and tryptophan. Tests indicated that free amino groups in prolactin are essential to its activity.³⁰ More advance has been made in the chemical study of prolactin than in that of any other anterior pituitary hormone.

Applications and Actions.—For increasing the milk yield of domestic animals after lactation has been established or during declining lactation, prolactin has sometimes³¹ but not always proved efficacious; likewise, from whole pituitary extracts both success and failure

are recorded;³² still other glandular products (notably thyroxine)³³ have sometimes proved of equal or of greater effectiveness for these unusual requirements. Again, the adrenal cortex—perhaps incident to its regulation of fluid and salts or to the production of sterols supporting mammary growth—seems to contribute something essential to the maintenance of milk flow or even to the initiation of this function in some species,³⁴ though apparently not in the dog.³⁵ Similarly, hypophysectomy, thyroidectomy or hysterectomy may markedly affect lactation. Finally, estrogen, though certainly helpful in the preparation of mammary tissue, becomes for one true action of prolactin an agent decidedly adverse to milk yield after lactation has been established.³⁶

Since it is thus obvious that so much of the organism—assimilative, endocrine and neural—becomes involved in the initiation, augmentation and maintenance of lactation, the term "lactogenic hormone" is equivocal and its use often a serious error; others (not ourselves) have rather generally ventured to employ this term as an alternative designation for that hormone which was found to initiate milk secretion in prepared mammary tissue and which after its isolation and establishment as an entity was called prolactin. Lactogenesis involves several hormones and many other factors; prolactin is a specific substance. Only full recognition of this distinction, along with awareness of other actions of prolactin, is likely to lead to satisfactory clinical use of this substance.

Clinical use of prolactin hitherto has been restricted largely to postpartum women with deficient lactation. In the earliest tests³⁷ twenty-nine women whose lactation had failed to develop adequately by the sixth to the ninth day were then given one or two intramuscular injections of prolactin, totaling 75 to 400 units. This dosage (highest, 200 units per injection) was well tolerated. In twenty-five of these women the daily milk yield increased by from 50 to 400 Gm. within three to nine days; there were four or five definite failures, in all of which the total dose used was only 100 to 150 units. In eight other women, whose milk secretion was or presumably would become normal, dosage for a single day with 100 to 400 units at one to fifteen days post partum probably induced no change. Werner³⁸ noted that eight castrates whose breasts were variously prepared (or unprepared) by previous estrogenic treatment did not lactate after intramuscular injection of 200 units of prolactin daily

for one to fourteen days; severe local and systemic reactions were produced in three of these women (two others reported on later). Evans³⁹ briefly reported seven successful tests with total doses of from 1,000 to 2,250 units. Hoffmann⁴⁰ noted that a total dose of 200 to 250 units given in two days may or may not increase the milk yield.

Two recent critical studies on the effects of twice-daily injections during two to four days, beginning on the sixth or seventh day post partum, led to somewhat different conclusions, though there were several obvious failures in both series of tests. Ross,⁴¹ using intramuscular injections during two days, gave a total dose of 400 units to nine patients and 1,000 units to twelve others. Only the larger dose appeared to result in an appreciable increase in milk secretion, and only this dose produced any adverse local reactions; the latter involved redness and indurations varying in diameter from 2 to 15 cm., and a rise in temperature to 100 to 102 F. for two to six days. Considered of special significance was the observation that a higher proportion of the mothers given the larger dose were able to nurse their infants after discharge from the hospital. Stewart and Pratt,⁴² giving a subcutaneous injection of 1,000 units daily from the sixth to the ninth postpartum day inclusive, got no significant increase in milk secretion from a group of fourteen patients whose secretion was less than 250 cc. on the fifth day. A similar group of ten mothers served as controls, and after leaving the hospital their nursing record was not significantly different from that of the group given prolactin. Stewart and Pratt conclude that the action of prolactin in animals is not analogous to that in women.

The most recent study is also the most complete and informative. Kenny and King⁴³ treated forty-three women with prolactin for deficient lactation, beginning at different stages up to the third month post partum; forty-three other women, to whom other "galactogogues" were given or on whom routine methods of encouraging lactation were practiced, served as controls. In 74 per cent of the treated women and in only 21 per cent of the controls lactation became sufficient for the whole need of the baby until weaning at the sixth to the seventh month. The complete failures included 19 per cent of the treated women and 63 per cent of the controls. The total dose of prolactin was 900 units, which was given intramuscularly at the rate of two injections a day for five days, as follows: on the first and second days 300 units a day, on the third and fourth days 120 units a day and on the fifth day 60 units. No local or systemic ill effects were observed. The milk produced was of normal composition and quality. They recommended that treatment begin early in order that efficient nursing might be established before discharge from the hospital.

Other actions of prolactin have been reported from animal experimentation, though appropriate clinical applications have not yet been published. In adult birds prolactin has powerful antigonad action, made evident by extremely rapid and nearly complete atrophy of the testes⁴⁴ and by speedy inactivation and regres-

sion of the ovary.⁴⁵ In adult male rats 10 to 20 units of prolactin daily for eight to fifteen days does not decrease the weight of the testes.⁴⁶ In female mice⁴⁷ and rats⁴⁸ dosage with prolactin stops estrous cycles. Small amounts of luteinizing substance also stop the cycles of mice, and since luteinizing substance is a contaminant of many prolactin preparations it has been suggested⁴⁹ that this action on the cycles of rodents is exercised by the luteinizing substance. Though it is clear that prolactin is, and luteinizing substance is not, effectively antigonad in birds, this action of prolactin is still uncertain in mammals.

Prolactin seems to be specifically involved in the onset or production of broodiness in the fowl,⁵⁰ the maternal or parental instinct in rats⁵¹ and nesting behavior in fish.⁵² Other anterior pituitary extracts, the urinary luteinizing substance, estrone (theelin), progesterone and extract of adrenal cortex all seem ineffective or inhibitory in the fowl, though phenol is active in fish, and pituitary luteinizing extract, intermedin, progesterone, desoxycorticosterone acetate and phenol are all fairly effective in rats.

Prolactin has marked calorogenic action in pigeons—normal, hypophysectomized or thyroidectomized—and its synergistic action with thyrotropin on heat production has been reported in normal doves.⁵³ The relation of prolactin to carbohydrate and fat metabolism is an important but still unsettled problem.⁵⁴ Splanchomegaly exhibited in the liver, pancreas and intestine of the pigeon is associated with the action of prolactin.⁵⁵ Body weight and appetite are especially increased by prolactin in pigeons, and favorable effects of this substance on the growth of the dwarf mouse—with a synergistic effect on growth when prolactin is administered together with thyrotropin—have been reported.⁵⁶

Large doses of ox pituitary prolactin (probably not entirely free from serum protein) injected daily into adult rabbits or young female monkeys for eighteen or more weeks resulted in the production of antisera capable of inhibiting the growth response in the crop sac of the pigeon and probably of reducing milk secretion in lactating mice.⁵⁷ Preparations of prolactin from ox and sheep glands, apparently free from serum protein, were found to be antigenically indistinguishable, and the serum of rabbits given injections of prolactin from either source usually partly inhibited prolactin action on crop sacs.⁵⁸

MAMMOGENIC HORMONES

The Mammo-genic Response.—Numerous old and new studies clearly prove that hormones of the ovary play a part in the growth of the mammary gland—in most species an estrogen induces (directly or indirectly) duct growth, and an estrogen plus progesterone induces lobule-alveolar development. Androgens, too, were later proved capable of replacing estrogens in the induction of growth in the mammary parenchyma. Still more recently desoxycorticosterone acetate and some phenanthrene and stilbene compounds not now known to occur in the body are reported to cause duct development in normal and castrate males of the species studied.

In hypophysectomized animals, however, the use of estrogens or androgens to develop mammary tissue has usually, though apparently not always, resulted in failure. Such failures together with the recovery of potent lipid extracts from the anterior lobes of pituitary glands which have been recently subjected to ovarian hormones—and other related facts—lead some investigators to believe that the pituitary gland secretes, in addition to its various hormones of protein nature, other (alcohol-ether soluble) hormone(s) with specific ability to induce mammary growth. In this review one needs to consider only literature bearing on (1) the question of whether estrogens, androgens and available phenanthrenes act directly or indirectly on mammary tissue and (2) the intimately related question of the elaboration of specific mammo-genic hormone(s) by the pituitary.

Direct or Indirect Action of Sterols.—Duct development was reported in 4 of 5 hypophysectomized male rats treated for fourteen days with 50 mouse units of estrone twice daily⁵⁹ and in mammary glands transplanted into similar rats.⁶⁰ Rapid mammary involution was observed in rats after hypophysectomy on the sixth day of lactation despite the injection of 100 micrograms of estrone daily; the conclusion was drawn that the pituitary is necessary for the action of estrone on the mammary gland.⁶¹ Mammary involution would be expected to follow the withdrawal of prolactin and the generally adverse effects of hypophysectomy, and it was later reported⁶² that the involution of the lobule-alveolar system of such rats is not rapid but requires at least as long as does its development. Houssay⁶³ observed

test and mammary enlargement in a male hypophysectomized dog given 10,000 international units of estrone daily for fifty-four days.

Estrone plus progestin was observed to cause further mammary development in hypophysectomized castrate rats than did estrone alone,⁶⁴ and the same was observed in guinea pigs similarly operated on.⁶⁵ In 4 hypophysectomized, ovariectomized rabbits given daily for fifteen days injections of 25 rat units of estradiol benzoate and 4 rabbit units of progestin, mammary development approximately equal to that in rabbits incompletely operated on or not operated on was reported.⁶⁶ Corner⁶⁷ had shown much earlier that in castrate rabbits with intact hypophyses progestin alone is without effect, and others⁶⁸ had observed that estrone plus progestin did cause development of the mammarys of such rabbits.

Later studies (since 1935) with estrogens on pituitaryless animals have more often given negative results on mammary growth, but the significance of these failures has been interpreted variously. Mammary growth in such rats was not stimulated by 25 to 500 international units of estradiol benzoate daily for fifteen to forty-five days,⁶⁹ by 20 to 100 units of estrone for twenty to twenty-five days⁷⁰ and only slightly after estrone,⁷¹ even when the general condition of the rat was sustained with pituitary extract.⁷² Selye and Collip⁷² therefore reaffirmed the view that this action of estrone must be through the pituitary. Astwood and his associates⁷³ emphasized the great importance of reduced nutrition incident to hypophysectomy. They observed mammary regression in normal rats on restricted diet during fourteen days, although 5 micrograms of estrone was injected daily. Likewise, in hypophysectomized rats the duct system regressed under estrone dosage, and the authors concluded that such failures provide insufficient evidence that mammary growth is mediated by the pituitary. Other failures of estrogens to support or increase mammary growth in pituitaryless animals were observed in guinea pigs, mice, rabbits, cats and ground squirrels.⁷⁴ Herold and Effkemann⁷⁵ reported no effect of estrogen in normal male and castrate female rats after severing the nerve connection between the pituitary and the midbrain and suggested that estrone acts by way of the diencephalon

from which impulses reach the pituitary and cause it to secrete a mammary growth factor.

When the pituitary was removed during pregnancy, the effects on mammary growth were unexpected and important. In rats operated on during the second week mammary growth was unaffected, and the usual accumulation of metabolic products in the lobular cells occurred.⁷⁶ In guinea pigs operated on at the fortieth day, with mammarys examined nine to twelve days later, a condition resembling that of normal glands at parturition was found.⁷⁷ In mice it was observed that even after digital abortion of fetuses and hypophysectomy on the twelfth day normal mammary changes occurred if the placentas had been retained;⁷⁸ the presence of the ovaries had earlier been found unessential for mammary growth at this period.⁷⁹ These results recall earlier evidence for an influence of the placenta on both mammary growth and secretion in animals with intact pituitaries.⁸⁰ That this influence may result from the secretion of an estrogen by the placenta, or otherwise, is obvious.

Testosterone and other androgens have been observed to cause mammary development in normal or ovariectomized rats.⁸¹ In hypophysectomized rats little or nothing more than nipple growth is obtained.⁸² In young male mice, not operated on, and in castrated male mice weighing from 15 to 25 Gm., the development of the mammary glands was accomplished with a wide variety of estrogens and androgens and with desoxycorticosterone acetate.⁸³ This result with the last named substance has special importance because (1) it adds the adrenal cortex to the few possible sources of mammogenic stimulation, (2) these cortical products are heat labile (in contrast with many estrogens) and more soluble in fat solvents, (3) such products are probably released from the cortex in increased amounts by estrone dosage in normal rats and pigeons but not or to a less extent after hypophysectomy,⁸⁴ (4) desoxycorticosterone (the only adrenal derivative hitherto tested) was observed in the study cited to have greater mammogenic potency per milligram than either of the five androgenic substances tested and (5) mice of just this type are used for assay of the mammogenic activity of the pituitary tissues and extracts to be described in the following section.

Mammogenic Potency of Pituitary Tissues and Extracts.—Implantation of pituitary tissue was followed by no appreciable mammary development in many tests made on rats.⁸⁶ In other tests, positive results in both ducts and lobules were secured on hypophysectomized male castrate and noncastrate guinea pigs following implantation of tissue from rats previously treated with estrogen.⁸⁶ In pituitaryless male and female guinea pigs a few tests with an extract of adrenal cortex (eschatin) alone or in combination with an estrogen (not named) indicated no mammary growth. Some further tests were reported, together with citations from the literature, indicating the ineffectiveness of thyroxine and of the recognized pituitary substances.⁷⁰ In a later study immature ovariectomized rats and spayed rabbits showed complete mammary development following implantation during twenty-five to thirty days of fresh (or acetone-dried) anterior pituitary tissue from pregnant cows.⁸⁷ In view of these results a new pituitary principle promoting growth in the mammary gland was postulated by Gomez and Turner and called "mammogenic hormone," or mammogen.

Nelson⁸⁸ reported that the mammary development of hypophysectomized immature female rats in which pituitaries from estrogen-treated rats of either sex had been implanted did not exceed or even equal that which followed implantation of normal rat pituitaries. He also announced his failure to confirm the claim of the existence of a specific "mammogenic hormone." Repeating this study, Reece and Leonard⁸⁹ also found no difference in the potency of pituitaries from untreated and estrogen-treated donors, but they noted that implanted glands of both types gave evidence of some growth when the test animals were compared with their untreated hypophysectomized control.

Albino mice were found to respond to pituitary implants and were considered most suitable for assay of mammogen.⁹⁰ The technic of this assay of the factor promoting duct growth involves the daily subcutaneous injection of macerated fresh anterior lobe tissue from pregnant cows or of mammogen-containing extracts for six days with autopsy on the seventh. The mouse unit is defined as the amount of tissue or extract required (per mouse) to produce definite signs of duct development in one or more glands of 50 ± 10 per cent of ten or more male albino mice weighing 15 to 25 Gm.⁹¹ With this technic the mammogen content of the pituitaries from pregnant cows was found greatest at one hundred and fifty days; that of the dairy cow was greater than that of the pregnant beef cow; that of beef heifers with corpora lutea was 40 to 60 per cent greater than that of pregnant beef cows at the one hundred and fifty day peak; steer, bull and fetal

91. Lewis, Turner and Gomez.⁹⁰ Lewis and Turner.⁹²

pituitaries showed appreciable amounts of mammogen.⁹² The authors suggested that estrogens lead to the production of a pituitary factor promoting duct growth, progesterone to a factor promoting lobule proliferation.

Lewis and Turner⁹³ observed that acetone and ether drying of prehypophyseal tissue resulted in a loss of 60 per cent of its mammogen content. Extraction of the tissue with several volumes of hot ether-alcohol (1:3) resulted in a preparation (oily residue) containing 1 unit per 3 to 4 mg. and including practically 100 per cent of the potency of the fresh tissue. In their most recent publication⁹² they have stated that their most potent preparation, tested in fourteen mice, gave positive results in 79 per cent at a dosage of 0.25 mg. per mouse. The estrogen content of some preparations was measured and considered far too low to have caused the mammary growth observed. The fact that fresh pituitary tissue containing mammogen caused both duct development and lobule hyperplasia, though the lipid extracts cause only duct development, was regarded as evidence that the lipid solvent separates a duct growth factor from a lobule growth factor.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

LIVER AND STOMACH PREPARATIONS (See New and Nonofficial Remedies, 1940, p. 320).

SOLUTIONS FOR PARENTERAL ADMINISTRATION

TEN CC. SOLUTION LIVER EXTRACT PARENTERAL-LEDERLE.—A sterile aqueous solution containing the nitrogenous nonprotein fraction G of Cohn et al. obtained from fresh mammalian liver, preserved with 0.5 per cent of phenol. The daily parenteral administration of 0.3 cc. has been found to produce the standard reticulocyte response defined as 1 U. S. P. unit (injectable) when assayed in cases of pernicious anemia as required by the Council.

Actions and Uses.—Solution liver extract parenteral-Lederle is proposed for intramuscular injection in the treatment of pernicious anemia. (See general article Liver and Stomach Preparations, New and Nonofficial Remedies, 1940, p. 320.)

Dosage.—To insure optimum dosage for cases of pernicious anemia in remission it is advisable to make an injection of 5 cc. each day for three or four successive days. In a series of cases in which remissions have been thus initiated by the use of solution liver extract parenteral-Lederle there is evidence that injections of 5 cc. every two weeks (or 1 cc. twice weekly if low unit, more frequent dosage is preferred) provide sufficient active material to complete the remission and maintain a satisfactory blood picture. In complicated cases and those with extensive neurologic involvement, the optimum dosage may be much larger and must be determined for each patient.

Manufactured by the Lederle Laboratories, Inc., Pearl River, N. Y.

Vials Solution Liver Extract Parenteral-Lederle, 10 cc.
Concentrated solution liver extract parenteral-Lederle is prepared as follows: A mixture of finely ground liver and water is acidified to the isoelectric point, pH 5.0-5.4. After partial coagulation of the liver proteins is effected by heating to 75-85°C. the pulp is separated by filtration, centrifugation or pressing and the aqueous filtrate is concentrated in vacuo to the consistency of a thin syrup. By careful fractional precipitation with large volumes of alcohol at low temperatures (4°C.) much inactive material (proteins) is precipitated and subsequently discarded. The alcoholic filtrate is concentrated in vacuo and sufficient alcohol added to precipitate the active material (fraction G)

of Cohn et al. (Proceedings of the American Society of Biological Chemistry, *J. Biol. Chem.* 74:1xix [July] 1927). The washed precipitate generally known as "Cohn's fraction G," commonly obtained as a hygroscopic, brownish powder, in addition to the active antianemic factor, contains much inert matter. In order to obtain a concentrate of the active factor as free as possible from inert substances, the solution containing the fraction G of Cohn is treated with a special activated carbon.

After filtering off the carbon the solution containing the active principle is concentrated in vacuo to a point where approximately 2.7 cc. represents the active material obtained from 100 Gm. of liver. Subsequently sufficient phenol is added to make 0.5 per cent in the finished product; volume is adjusted and the solution is sterilized by Berkefeld filtration.

SOLUTIONS FOR PARENTERAL ADMINISTRATION

(See New and Nonofficial Remedies, 1940, p. 327)

PARENTERAL SOLUTION OF LIVER, 5 U. S. P. UNITS PER CC.-NATIONAL DRUG CO.—A sterile aqueous, clear, dark brown solution containing all of the fraction G of the liver extract (Cohn), preserved with 0.5 per cent of phenol. The daily parenteral administration of 0.2 cc. has been found to produce the standard reticulocyte response defined as 1 U. S. P. unit (injectable) when assayed in cases of pernicious anemia as required by the Council.

Actions and Uses.—Parenteral solution of liver-National Drug Company is proposed for intramuscular injection in the treatment of pernicious anemia. See the general article Liver and Stomach Preparations (New and Nonofficial Remedies, 1940, p. 320).

Dosage.—Daily intramuscular injections of 1 cc. for three to four days may be sufficient for the average case. For more severe cases the doses may be raised to from 2 cc. to 4 cc. It is desirable to give at least 20 units (4 cc.) on the first and second days, but it may be advisable in the case of patients who are to receive the larger doses to divide the dose and give one half of the amount into each gluteal muscle. After seven days' interval, 10 units (2.0 cc.) may be administered at weekly intervals. The dosage of course will vary with the individual patient, depending on the degree of complications.

Distributed by the National Drug Company, Philadelphia.

Amput-Vial Parenteral Solution of Liver-National Drug Company, 10 cc. (5 U. S. P. Injectable Units per cc.).

Parenteral solution of liver-National Drug Company in bulk is passed through a Berkefeld filter into a large sterile container and then it is tested for sterility. If the solution is found to be sterile, it is injected intracutaneously in rabbits and subcutaneously in guinea pigs. Rabbits are tested for necrosis; guinea pigs are checked for edema and general reactions. When these tests show that the material is free from reactions, the solution is filled aseptically into sterile 10 cc. ampul vials. After filling, the material is tested for sterility. Ten containers are selected from the entire lot and each is tested for sterility. If any of these ten tested containers shows growth, ten more bottles are tested. If growth appears on retesting these new ten ampul vials, the entire lot is then reprocessed.

PARENTERAL SOLUTION OF LIVER, 10 U. S. P. UNITS PER CC.-NATIONAL DRUG CO.—A sterile aqueous, clear, dark brown solution containing all of the fraction G of the liver extract (Cohn), preserved with 0.5 per cent of phenol. The daily parenteral administration of 0.1 cc. has been found to produce the standard reticulocyte response defined as 1 U. S. P. unit (injectable) when assayed in cases of pernicious anemia as required by the Council.

Actions and Uses.—Parenteral solution of liver-National Drug Company is proposed for intramuscular injection in the treatment of pernicious anemia. See the general article Liver and Stomach Preparations (New and Nonofficial Remedies, 1940, p. 320).

Dosage.—Daily intramuscular injection of 0.5 cc. for three to four days may be sufficient for the average case. For more severe cases the doses may be raised to from 2 to 4 cc. It is desirable to give at least 20 units (2 cc.) on the first and second days, but it may be advisable in the case of patients who are to receive the larger doses to divide the dose and give one half of the amount into each gluteal muscle. After seven days' interval, 10 units (1.0 cc.) may be administered at weekly intervals. The dosage of course will vary with the individual patient, depending on the degree of complications.

Distributed by the National Drug Company, Philadelphia.

Amput-Vial Parenteral Solution of Liver-National Drug Company, 10 cc. (10 U. S. P. Injectable Units per cc.).

Parenteral solution of liver-National Drug Company, in bulk as purchased is passed through a Berkefeld filter into a large sterile container and then it is tested for sterility. If the solution is found to be sterile, it is injected intracutaneously in rabbits and subcutaneously in guinea pigs. Rabbits are tested for necrosis; guinea pigs are checked for edema and general reactions. When these tests show that the material is free from reactions, the solution is filled aseptically into sterile 10 cc. ampul vials. Ten containers are selected from the entire lot and each is tested for sterility. If any of these ten tested containers shows growth then ten more bottles are tested. If growth appears on retesting these new ten ampul vials, the entire lot is then reprocessed.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - - CHICAGO, ILL.

Cable Address - - - - "Medic, Chicago"

Subscription price - - - - : Eight dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, DECEMBER 28, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

CHANGES IN MAKEUP OF THE JOURNAL

Beginning with the issue for Jan. 4, 1941, the first, third and fourth cover pages of THE JOURNAL will be printed in two colors, utilizing the two color presses just installed. The change is not a radical one, involving only the use of the extra color in order to develop certain features. The general makeup and style of the cover of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION have prevailed for more than forty years and constitute such a well established form that any radical change in the nature of display type, streamlining or similar innovations has not been contemplated. In connection with the use of the additional color, the quality of the paper used for the cover has also been improved, and a finer quality of ink will be utilized.

Consideration was given also to the desirability of changes in the arrangement of the material in the reading pages. For convenience in the handling of the

large amount of material which must now be rushed into THE JOURNAL because of the timeliness of articles dealing with medical preparedness and medical organization, the sections entitled "Book Notices" and "Queries and Minor Notes" have been shifted to a place just previous to the advertising pages in the back of the book. Since much of this material is constantly on hand, it is possible to make up these pages somewhat in advance of the time when the pages dealing with more current material are prepared.

This week's issue of THE JOURNAL is the index number. Readers will find that they have received for a six months period some 2,400 pages of original contributions, editorials, news material, abstracts, answers to questions, reviews of books, medicolegal information and the reports of the various councils of the American Medical Association. THE JOURNAL is proud to say that such a quantity of material of an authoritative, timely and practical character is not made available by any other medical publication in the world, even at twice the price.

THE OPTIMUM POPULATION FOR THE UNITED STATES

The changed complexion of national life which is portended by present trends in population has been discussed frequently by THE JOURNAL.¹ All the evidence of probabilities foreshadows a more or less static population or possibly a slight decrease late in this century, with a shift in age groupings resulting in a larger percentage of the total in the older years and a smaller one of children. This prospect, though contrary to an accustomed pattern, need not give rise to alarm. If, for example, the productive age group is considered to be between the ages of 20 and 65, the percentage of the total population between these ages is sure to increase for another ten years at least and will, even in the event of a slight decrease in total population, remain amply sufficient to support the groups of the population which are dependent on account of age. The percentage in the groups dependent by reason of age may not change much: with an increase in the number of elderly dependents a decrease in the number of children who are dependents is likely to occur. From a careful consideration of the probabilities, Burch² concludes that serious economic problems are not likely to result from this change in proportion of "youngsters" and "oldsters" and that there is little chance of dependent old people controlling the economic and political situation. Those over the age of 65 can never hope to cast more than a quarter of the total vote of the nation, even if no changes are made to restrict their political influence—a possibility with which one must reckon.

2. Burch, G. I.: Changing Age Composition of the American People, Population Bulletin, March 1940, Population Reference Bureau, Washington, D. C.

A favorable relationship between the number of people and the natural resources is vital to a democracy, Burch³ believes. Although the unparalleled prosperity which the United States has enjoyed in the past has been closely associated with a rapid increase in population, it should be obvious that its continuation is not dependent on a similar rapid rate of population growth and would indeed even be hindered by a too rapid growth. Recent studies of diet, of land that can be safely cultivated and of this country's capacity to produce and consume have thrown new light on the subject of optimum population for the United States. As pointed out in a study of the Brookings Institute, it would seem that a reasonable minimum aim of our national economy would be to provide the entire population with a liberal diet which would furnish adequate nutrition, a substantial margin of safety in respect to vitamins and minerals, and a satisfying variety of foods. To reach the minimum standards proposed would require an increase in the volume of production over that existing in 1929 of all kinds of consumer goods and service by something like 70 to 80 per cent. In brief, and employing optimistic assumptions which are far removed from existent fact and may not be possible of attainment, it would require a national income of some 146 billion dollars to support 128 million persons at the minimum "optimum" standard of living and assuming an even distribution. However, the population has already exceeded this number (about 132,000,000) and the national income is only about half of the suggested figure. Furthermore, it is almost certain that the population will grow by at least 20 million more by 1980 not including foreign immigration, and even this estimate postulates a decrease of about 25 per cent in the birth rate over the next forty years.

From these studies it may be concluded that the slowing of population growth now manifest is almost certainly a desirable feature in maintaining the superior economic opportunities which place this country in a relatively favorable position as compared with the crowded countries of Europe. The figures also show that there is no need to fear either a lack of available workers or a lack of potential soldiers to meet any threat. Burch⁴ likewise rejects the hypothesis that a high birth rate is a measure of vitality and a low birth rate a measure of national decadence. Economic and social conditions appear to be the real controls of the birth rate and population growth. With the picture of the true meaning of population trends becoming gradually clarified, future emphasis might be placed on quality of the population rather than on quantity alone as measured by the gross number of births. It is at least certain that there will be no shortage of workers or consumers and no overwhelming proportion of dependents in this country in the immediately visible future.

TRAFFIC IN NARCOTIC DRUGS

The U. S. Bureau of Narcotics has recently reported on the traffic in opium and other dangerous drugs for the year ended Dec. 31, 1939.¹ Contained in this report is a most interesting contrast of the prevalence of addiction to narcotic drugs in 1877² and at present. In 1877, according to the report, one in every 400 persons in the United States was addicted to opium or one of its derivatives, while in 1922 and 1938, subsequent to enactment of the Harrison Narcotic Act in 1914, the ratio of such addicts to population was respectively 1 in every 1,000 and 1 in every 3,000. In the state of Michigan in 1877 there were 516 narcotic addicts per hundred thousand of population but in 1938, according to a survey conducted in Michigan by the Bureau of Narcotics in that year, there were only 17 addicts per hundred thousand. Opium or morphine eaters, prevalent in 1877, were not discovered in that survey; most of the addicts used heroin which was highly adulterated. In 1877 this country, with a population of 46,000,000, imported 350,000 pounds of raw opium but during the past few years, since importation of that drug was by law restricted to amounts necessary for medicinal and scientific needs, such imports have averaged only 150,000 pounds yearly for more than 130,000,000 people. In 1877 the average per capita consumption of opium and its derivatives was 53 grains as compared with an average consumption in 1939 of only 8.4891 grains, or 550.091 mg., per capita. The consumption of opium is no longer greatly out of proportion to medical needs. Because the supplies of heroin and morphine, the derivatives of opium commonly used by addicts, are so restricted and the prices so prohibitive, contraband drugs at the time they reach the addict are usually adulterated about 95 per cent. Consequently the average addict today obtains what amounts to less than 1 grain of his drug of addiction daily. Because of the scarcity, dilution or prohibitive price of heroin and morphine, narcotic addicts frequently resort to the use of paregoric, laudanum or the various barbituric acid derivatives. Today there are fewer female than male drug addicts, the ratio being about four males to one female, while in earlier times the reverse was the case owing to the promiscuous use of opiates for the relief of diseases of the female reproductive organs.

In 1877 physicians in many instances were directly responsible for formation of the narcotic habit by patients. Physicians too frequently resorted to the use of narcotic drugs, continued medicines too long, or, which occurred more often, prescribed indiscriminately, so that the patient continued the use of the drug indefinitely. Physicians' prescriptions for narcotic drugs were commonly refilled again and again by druggists.

4. Burch, G. I.: The Birth Rate as a Measure of National Vitality, *Population Bulletin*, April 1940.

1. Anslinger, H. J.: Traffic in Opium and Other Dangerous Drugs for the Year Ended Dec. 31, 1939. U. S. Treasury Department, Bureau of Narcotics, U. S. Government Printing Office, Washington, 1940.

2. Sixth annual report of the Michigan State Board of Health for the fiscal year ended Sept. 30, 1878.

Today, however, the majority of narcotic addicts are of the criminal element and are unknown to physicians and druggists. The medical profession generally is now alive to its responsibilities, and physicians, with the exception of a small minority, are more alert to the dangers surrounding the use of narcotic drugs. The indiscriminate use of narcotic medicines without intelligent medical advice, to which the spread of addiction in 1877 was attributed, is no longer prevalent. Only about 5 per cent of those addicted in 1939 gave this as a reason for their addiction. The Bureau of Narcotics attributes this improved condition in part to the efforts of the American Medical Association in publishing and distributing to the medical profession a book entitled "The Indispensable Use of Narcotics"³ and to better instruction in medical schools. No longer is there frequent dosing of infants with opiates and no longer are family medicine cabinets and nurseries stocked with patented soothing syrups, cordials, anodynes and other preparations containing opium or its derivatives. In 1877 laudanum was a favorite drug of addiction but, to the knowledge of the Bureau of Narcotics, no addict in 1939 acquired his habit originally from the taking of this drug. The creating of an addict during childhood and continuing into the adolescent stage, which was common in 1877, no longer occurs. However, opium, particularly its derivative codeine, is still, and rightly so, the most important drug used by the medical profession.

In 1877 those who had become addicted to opium or its derivatives generally gave as their excuse for acquiring the habit that they had taken their drug of addiction in the beginning to relieve some painful or incurable disease. In 1939, according to the Bureau of Narcotics, over 60 per cent of narcotic addiction was due to association with other addicts. The use of narcotics by prostitutes is still a factor in the narcotic traffic. Narcotic addiction is still formed sometimes when a drunkard resorts to drugs for sobering effects. According to the Uniform Crime Reports for 1939, issued by the Federal Bureau of Investigation of the Department of Justice, the majority of narcotic law violators are major criminals. Of such violators arrested during 1939, 64.6 per cent had previous records and arrests.

A significant problem which still persists is the prescribing or dispensing by a relatively small number of physicians, in violation of the Harrison Narcotic Act, of large quantities of narcotic drugs to addicts, not in the course of bona fide medical treatment but solely to cater to drug addicts and to satisfy their craving for their drug of addiction. During 1939 the Bureau of Narcotics reported to the licensing agencies of the several states, for disciplinary action against physicians, 77 cases of conviction for narcotic irregularities, 62 cases of addiction and 13 cases of conviction or addic-

tion in other states, of which 3 involved unlicensed physicians. During the year, with respect to cases of conviction, the state licensing agencies revoked the physician's license in 21 cases, suspended the physician's license in 4 cases, placed the physician on probation in 15 cases, in 10 of which narcotic privileges were withdrawn, admonished the physician in 1 case, dismissed the case without disciplinary action in 13 cases, and in 5 other cases the physician died before action could be taken. With respect to cases of addiction, the following disciplinary action was taken by the state licensing agencies: revocation of licenses 4, suspension of licenses 4, probations without narcotic privileges 12, probations 10, admonitions 2, dismissed without disciplinary action 20 and in 6 cases the physician died pending action. In the cases of conviction or addiction in other states the state licensing agencies revoked the physician's license in 5 cases, suspended the practitioner's license in 1 case and placed the physician on probation without narcotic privileges in 1 case. On Dec. 31, 1938 the cases pending action before the state licensing boards were 128 cases of conviction, 123 cases of addiction and 17 cases of conviction or addiction in other states, while on Dec. 31, 1939 the cases still pending action numbered 146 cases of conviction, 124 cases of addiction and 21 cases of conviction or addiction in other states. The Bureau of Narcotics calls attention particularly to the failure of one state licensing agency to take any action whatever in 3 cases of conviction of flagrant violation of the Harrison Narcotic Act by physicians in that state which were reported to that agency for disciplinary action. In 1 of those cases the physician issued in one year 996 prescriptions for 52,100 grains of morphine, or 208,400 doses of a quarter grain each.

In the United States the abuse of marihuana (*Cannabis sativa* L.) consists principally in the smoking of the resinous flowering tops and crushed portions of the plant, rolled into cigarettes. The Bureau of Narcotics reports that, since the enactment of the Marihuana Tax Act of 1937, considerable progress has been made toward a solution of this nationwide problem. During the year 1939 federal and state narcotic officers seized 23,289 Kg. 606 Gm. of bulk cannabis, 34 Kg. 841 Gm. of cannabis seeds, 22,567 marihuana cigarettes and approximately 930,880 cannabis plants. Also 9,026 metric tons of cannabis growing on 4,542 hectares of land were eradicated. It is estimated that the total area of uneradicated cannabis growth in this country is approximately 18,211 hectares. During 1939 the Bureau of Narcotics continued its efforts to combat the marihuana smoking practice by preventive educational work, particularly regarding the evils of marihuana. The bureau believes that direct propaganda to youth is undesirable because of the danger of arousing undue curiosity, but that it is desirable for parents, without overemphasis, to educate the youth against the use of marihuana.

3. *The Indispensable Use of Narcotics*, by Various Authors, Chicago, American Medical Association, 1931.

THE JOURNAL commends the enlightened and effective administration of the Bureau of Narcotics. A record such as that here reported indicates effective control. The cooperation of the medical profession has been freely and fully rendered, owing no doubt to recognition by the medical profession of the desire of the bureau to destroy criminal practice without undue interference with the legitimate prescription of narcotic drugs. Complete cooperation with the bureau by state licensing agencies will do much to further this significant work.

Current Comment

PLASMA IN TREATMENT OF ACUTE HEMORRHAGE

The present World War has enormously stimulated studies on effective substitutes for blood transfusion in treatment of hemorrhage. Recently Buttle and his co-workers¹ from the Department of Physiology, Middlesex Hospital, reported an evaluation of various blood substitutes based on controlled experiments in animals. As a result of their work they placed the substitutes in the following order of therapeutic value: (1) plasma, (2) serum, (3) hemoglobin-Ringer, (4) "gum-saline," (5) red cells suspended in "crystalloid" solution, and (6) physiologic solution of sodium chloride or isotonic dextrose solution. By way of practical accord with these conclusions, Aylward and his colleagues² working in Manchester report careful laboratory investigations on the technic of the concentration and drying of plasma. The dried product has several important advantages: stability, economy of storage place, ease of transport, and facility in the preparation of concentrated plasma—the latter arising from the recent recognition that there may be advantages in the use of concentrated plasma which can be readily obtained by dissolving the plasma powder in sterile distilled water to give the required concentration. Any method of drying plasma must fulfil certain conditions, the Manchester investigators point out, namely temperature control, solubility and sterility. Two principal methods of drying are available: the concentration and drying by spray distillation in vacuo, using various types of apparatus, and the concentration and drying of plasma by the cellophane tube method under sterile conditions followed by low temperature drying of the concentrate. Both these methods, they say, enable large amounts of plasma to be concentrated and dried without undue cost. These methods can be applied also to serum. The Manchester workers point out that, while the clinical effects of serum and plasma transfusions are probably similar, there are certain advantages in collecting serum rather than plasma, since serum will dry somewhat more easily than plasma owing to the absence of fibrin, sodium citrate, sodium chloride and possibly dextrose. Additional refinements of technic in the development of

satisfactory and inexpensive methods of preparing blood substitutes are likely to result from the extensive studies now being made in many places.

EFFECT OF CHILDREN ON ECONOMIC STATUS OF AMERICAN FAMILIES

Many factors appear to be involved in the declining birth rate which has been apparent in Western countries for several decades. Lorimer¹ has recently reviewed the economic effect on American families of the appearance of children in various numbers. The most striking change in proportional expenditures in passing from families without children to families with one or more children is in the food item. At given income levels the proportions of the total family expenditures allotted to food rise consistently as the number of children in the family increases. This increased expenditure for food obviously must be offset by curtailment of other expenses. The reduction, however, is not constantly evidenced for any particular group of expenditures but appears at various points, notably household operation, furnishings and equipment, and transportation. In spite of the increased outgo for food, the average food consumption level is actually lowered as the number of children increases. Lorimer points out that if all family types invested an identical proportion of their total income in food, families with three or four children in some areas (Chicago cited specifically) would need just about twice the income of childless families in order to maintain the same consumption levels. Even farm families of several children would need more than 50 per cent larger incomes than childless families of like location. Moreover, the added expenditures for children's clothing are largely offset by reduction in the expenditure of husband and wife for their own clothing. The increased housing needs brought about by children usually result in the acceptance of more crowded quarters or moving to less satisfactory locations. The relation of total expenditure to income, i. e. the margin of savings or liability to debt, also reflects the number of children in a family. The degree of the economic effect of children varies with the income level and it influences and is influenced by the gainful employment of both parents. Indeed the entire economic outlook and practice are fundamentally involved by the addition of children to the family. Intelligent population policy requires that attention be given to these conditions. Lorimer believes it essential that some aid and support to families be established so that parents need not as at present jeopardize the standards of living which they set for themselves and their children if they wish to add new lives to the family. There are two possible approaches to equalization of levels of living among families with none or few children and large families: the family allowance proportionate to the number of children and the system of special service and subsidy to families with children along the lines developed in Sweden. In the problems which these facts present, policies concerned with population are paramount and require further research, experimentation and public attention.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

COMMITTEE ON AVIATION MEDICINE INSPECTS FACILITIES

Members of the committee on aviation medicine of the National Research Council recently made a tour of aviation medical facilities of the United States, Canada and Cuba. The group included Drs. Eugene F. Du Bois, New York, chairman of the committee; Cecil K. Drinker, Boston; John F. Fulton, New Haven, Conn.; Eugene M. Landis, Charlottesville, Va. They were accompanied by Comdr. J. F. Poppen of the U. S. Navy and Capt. Lloyd Griffis, U. S. Army. The facilities visited included Wright Field, Dayton, Ohio; the Naval Base at San Diego, Calif.; Guantanamo, Cuba, and the University of Toronto in Canada.

CIVILIANS AND HOSTILE AIRCRAFT

Dr. Gustave E. Ledorf, captain, Medical Corps, the Army Industrial College, Washington, D. C., gave a public lecture in Rochester, N. Y., December 1, under the sponsorship of the Rochester Academy of Medicine, the Medical Society of the County of Monroe and the University of Rochester School of Medicine. His subject was "Care of the Civilian Population Necessitated by Hostile Aircraft."

SARANAC LAKE MEDICAL SOCIETY

The Saranac Medical Society, Saranac Lake, N. Y., at a meeting in the Saranac Laboratory, November 13, adopted a resolution recommending that all men entering the army services receive a roentgen examination of the chest before induction into the service. The guest

speakers at this meeting were Drs. S. F. Marshall and E. D. Kiefer of the Lahey Clinic, Boston, and their subject was "Medical-Surgical Treatment of Peptic Ulcer."

FIVE NEW BRIGADIER GENERALS

Five colonels of the U. S. Army Medical Department have been promoted to temporary Brigadier Generals as of October 1, according to the *Military Surgeon*. They are Brig. Gen. Albert G. Love, who will remain on duty as chief of the planning and training division in the Surgeon General's Office; Wallace DeWitt, now at Letterman General Hospital, Presidio of San Francisco; William L. Sheep, who is to be commanding general of the new army general hospital to be established in the vicinity of Atlanta, Ga.; Morrison C. Stayer, chief medical officer of the Panama Canal, and Howard McC. Snyder, who has been detailed in the Inspector General's Department.

FIELD HOSPITAL SENT TO ENGLAND

The American Field Hospital Corps has presented to the British War Relief Society a mobile field hospital of forty-one units, twenty-five trucks and trailers and sixteen weather-proof tents. The hospital, valued at \$100,000, is equipped to accommodate 100 bed patients and a hospital staff of fifty. It is completely self contained and can be operated in devastated and isolated districts where shelter, power and other facilities for taking care of epidemics and the critically injured do not exist, according to the *New York Times*. The unit was taken to Staten Island, December 15, for shipment to England.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY WAR DEPARTMENT

The following additional medical reserve corps officers had been ordered to extended active duty with the regular army by direction of the War Department, Washington, D. C., up to December 13:

BELISLE, John Alexander, 1st Lieut., Mount Clemens, Mich.
CHASEN, William Henry, 1st Lieut., Brooklyn.
DALY, Joseph Michael, 1st Lieut., Laurel, Md.
EVANS, Charles Welton, Jr., 1st Lieut., Fastrill, Texas.

EWAN, John Radcliffe, 1st Lieut., Philadelphia.
GALIN, Jack, 1st Lieut., Jacksonville, Fla.
GILES, Robert W., 1st Lieut., Arkansas Pass, Texas.
GOODMAN, Eli, 1st Lieut., Chicago.
HAIMES, Solomon Manuel, 1st Lieut., Allentown, Pa.
LEVIN, Emanuel Jack, 1st Lieut., Philadelphia.
LOOMER, Harry Pincus, 1st Lieut., Brooklyn.
NICHOLS, Ace Elliott, 1st Lieut., Corpus Christi, Texas.
THOMASSY, George Ernest, 1st Lieut., Washington, D. C.
TOLOFF, Edward Myron, 1st Lieut., Pittsburgh.

FIRST CORPS AREA

The following additional medical reserve officers had been ordered to extended active duty with the regular army by the Commanding General, First Corps Area, up to December 6. The First Corps Area comprises the states of Maine, Vermont, New Hampshire, Rhode Island, Massachusetts and Connecticut.

ABRAMS, Herbert, Lieut., Lowell, Mass.
ALPERT, Max, Lieut., Bridgeport, Conn.
ANGELO, Peter, Lieut., Allston, Mass.
BERMAN, Bernard A., Lieut., Waterbury, Conn.
COYNE, Arthur A., Captain, Northampton, Mass.

HENDERSON, John W., Captain, Worcester, Mass.
HOWARD, James H., Lieut., Pittsfield, Mass.
JOSLIN, Allen P., Lieut., Boston.
MEISTER, Abraham J., Lieut., Lawrence, Mass.
PAGLIARO, Joseph J., Lieut., Derby, Conn.
PHILLIPS, Robert T., Captain, Portland, Maine.
ROSEN, Abraham E., Lieut., Bangor, Maine.
ROZEN, Alan A., Lieut., New Haven, Conn.
SEGEL, Arnold L., Lieut., Boston.
SIMARD, Louis Basil, 1st Lieut., Haverhill, Mass.
STEWART, Artemas J., Captain, Lowell, Mass.
THOMPSON, Bob F., Lieut., New Haven, Conn.
WESOLY, Andrew S., Lieut., New Britain, Conn.
WILLARD, Paul C., Lieut., Montpelier, Vt.
WITTIG, Joseph E., Lieut., West Warwick, R. I.

SECOND CORPS AREA

The following additional medical reserve officers had been ordered to active duty by the Commanding General, Second Corps Area, up to December 13. The Second Corps Area comprises the states of New York, New Jersey and Delaware.

ALEXANDER, Stewart F., 1st Lieut., Park Ridge, N. J.
AMDUR, Marvin L., 1st Lieut., Buffalo, 1st Military Area.
ANGELO, Martin A., 1st Lieut., Buffalo, 1st Military Area.
BABBITT, Hugh M., 1st Lieut., Plainfield, N. J., 3d Military Area.
BACKER, Max B., 1st Lieut., Brooklyn, 2d Military Area.
BARONE, Francis A., 1st Lieut., Jersey City, N. J., 3d Military Area.
BERGSTEIN, Joseph, Captain, Brooklyn, 2d Military Area.
BEYER, William, Major, Edgewater, N. J., 3d Military Area.
BLOOM, Bernard B., 1st Lieut., Brooklyn, 2d Military Area.
CHAMPLIN, Ray D., Lieut. Col., Oneonta, N. Y., 1st Military Area.
CHURCH, Sheldon, 1st Lieut., Albany, 1st Military Area.
DEIBERT, Kirk R., 1st Lieut., Woodllynne, N. J.
DESERVO, Thomas G., 1st Lieut., New York, 2d Military Area.
DOLTOLO, Joseph J., 1st Lieut., Poughkeepsie, N. Y.
ENGEL, Edward F., Captain, Seneca Falls, N. Y., 1st Military Area.
EUPHRAT, Edwin J., 1st Lieut., Flushing, N. Y.
FEINGOLD, Abraham, 1st Lieut., Brooklyn.
FORD, William G., 1st Lieut., Buffalo, 1st Military Area.
FRANK, Simon C., 1st Lieut., Williston, N. Y., 2d Military Area.
FRED, Leo, 1st Lieut., Brooklyn, 2d Military Area.
FREEMAN, Nathan, Captain, 1236 Pacific Street, Brooklyn.
GILLIS, Alfred G., Captain, Clayton, N. J., 3d Military Area.
GLENN, James A., Jr., 1st Lieut., North Creek, N. Y., 1st Military Area.
GOLDBERG, Irwin, 1st Lieut., New York, 2d Military Area.
GREENE, John E., 1st Lieut., Jamaica, N. Y.
HOFFMAN, Floyd W., 1st Lieut., Romulus, N. Y.
HOLLEY, Emerson, 1st Lieut., Lockport, N. Y., 1st Military Area.
HOWLAND, Reeve S., 1st Lieut., Elmira, N. Y., 1st Military Area.
KIVEN, Nathan J., 1st Lieut., Jamaica, N. Y., 2d Military Area.
MARKULIS, Emil J., 1st Lieut., Orchard Park, N. Y., 1st Military Area.
MARSHALL, Irving, 1st Lieut., Jersey City, N. J., 3d Military Area.

McGOWAN, John F., 1st Lieut., Buffalo, 1st Military Area.
MEISTER, Peter C., 1st Lieut., Buffalo, 1st Military Area.
MENDEN, Julian, Captain, New York.
MESSINA, John L., 1st Lieut., Brooklyn, 2d Military Area.
MORCHAN, Samuel, 1st Lieut., Angelica, N. Y., 1st Military Area.
NADLER, Arthur A., Captain, Plainfield, N. J., 3d Military Area.
NEDELL, Ralph S., 1st Lieut., Brooklyn.
O'TOOLE, John S., Jr., 1st Lieut., Potsdam, N. Y., 1st Military Area.
PATTI, Samuel R., 1st Lieut., Dunkirk, N. Y., 1st Military Area.
RITTER, Fred L., Major, Syracuse, N. Y., 1st Military Area.
ROACH, John S., 1st Lieut., Medina, N. Y., 1st Military Area.
SABIN, Anthony G., Captain, New York, 2d Military Area.
SAYER, John W., 1st Lieut., Gouverneur, N. Y., 1st Military Area.
SCHOEDEL, Adrian C., 1st Lieut., Flushing, N. Y., 2d Military Area.
SCHWARTZ, Leon J., 1st Lieut., Greenwich, N. J.
SHAEN, Edward, 1st Lieut., Camden, N. J.
STERN, Leon B., 1st Lieut., New York, 2d Military Area.
STOLA, Augustus G., 1st Lieut., New York, 2d Military Area.
TINKER, Martin B., Jr., 1st Lieut., Ithaca, N. Y., 1st Military Area.
SMUDA, Alphonse C., 1st Lieut., Glendora, N. J.
SOMMER, George N. J., Jr., 1st Lieut., Trenton, N. J.
SULLIVAN, Norbert P., Captain, Jackson Heights, N. Y., 2d Military Area.
TEGMEYER, Charles E., 1st Lieut., Hamilton, N. Y.
WEISS, Mortimer, 1st Lieut., Hudson Falls, N. Y., 1st Military Area.
WELGE, Carl J., 1st Lieut., Roosevelt, N. Y., 2d Military Area.

Orders Not Issued

Medical reserve officers reported in THE JOURNAL, Nov. 16, 1940, page 1727, as having been ordered to active duty but whose orders have not been issued:

CREIGHTON, James J., 1st Lieut., Buffalo.
DURHAM, James R., Jr., 1st Lieut., Wilmington, Del.
HAYMAN, Charles R., 1st Lieut., Scarsdale, N. Y.
KARPEL, Bernard, 1st Lieut., New York.
KURLAND, Harry A., 1st Lieut., New York.

FOURTH CORPS AREA

The following additional medical reserve officers had been ordered to active duty by the Commanding General, Fourth Corps Area, up to December 6. The Fourth Corps Area comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana:

ANDERSON, Henry L., 1st Lieut., Sellers, Ala.
BELL, Kenneth R., Captain, Sanford, Fla.
BENTON, Wayne J., 1st Lieut., Greensboro, N. C.
BERRY, Robert L., Jr., 1st Lieut., Villa Rica, Ga.
BISHOP, Louis D., 1st Lieut., DeQuincy, La.
BOOZER, Thomas S., 1st Lieut., Talladega, Ala.
BROWN, Stephen W., 1st Lieut., Milledgeville, Ga.
CLAPP, Hubert L., 1st Lieut., Swannanoa, N. C.
COGDILL, David M., 1st Lieut., Fayetteville, N. C.
CORNELL, William S., Captain, Charlotte, N. C.
DENHOLM, John S., 1st Lieut., Burlington, N. C.
DISMUKES, Jackson B., Captain, Haines City, Fla.
DOTSON, Walter S., Jr., 1st Lieut., Westmoreland, Tenn.
EDWARDS, William W., 1st Lieut., Greenville, S. C.
EVERS, Herbert R., 1st Lieut., Andalusia, Ala.
EXLEY, David W., 1st Lieut., Miami Beach, Fla.
FARMER, William A., 1st Lieut., Fayetteville, N. C.
GORDON, Joseph T., 1st Lieut., Pulaski, Tenn.
GRIFFIN, Louie H., 1st Lieut., Gibson, Ga.
GRIFFIN, Taylor W., 1st Lieut., Quincy, Fla.
HATFIELD, John R., 1st Lieut., Orlando, Fla.
HAY, Floyd B., 1st Lieut., Byrdstown, Tenn.
HEUER, Douglas F., Jr., 1st Lieut., Memphis, Tenn.
HIGHTOWER, Jesse R., 1st Lieut., Itta Bena, Miss.
JACOB, Harold J., 1st Lieut., Columbus, Miss.
KING, Lebbey B., 1st Lieut., Lake City, S. C.
LUSTGARTEN, Jack G., 1st Lieut., Buxton, N. C.
LYNN, Cy K., 1st Lieut., Valdese, N. C.
McMANUS, Hugh F., 1st Lieut., Raleigh, N. C.
MARTIN, Carl T., 1st Lieut., Haleyville, Ala.

MILLER, Edward S., 1st Lieut., Murphy, N. C.
MOORE, Haywood L., 1st Lieut., Porterdale, Ga.
NUNGESTER, Garrold H., 1st Lieut., Decatur, Ala.
ODEN, Lewis H., Jr., 1st Lieut., Blackshear, Ga.
PALMER, Yates S., 1st Lieut., Valdese, N. C.
PARKER, Shepherd F., 1st Lieut., Shelby, N. C.
PATTON, Marion L., Captain, Memphis, Tenn.
PEASLEY, Elmus D., Major, Raleigh, N. C.
PENTECOST, Ben L., 1st Lieut., Memphis, Tenn.
QUILLIAN, William B., Jr., 1st Lieut., Cartersville, Ga.
ROBERTSON, Carroll B., 1st Lieut., Jackson, N. C.
ROBBINS, Eric P., 1st Lieut., Brockhaven, Miss.
RUSSELL, Alexander B., 1st Lieut., Winder, Ga.
RUSSELL, Ralph E., 1st Lieut., Ocala, Fla.
RUSSELL, Ralph S., 1st Lieut., Ocala, Fla.
SCHUESSLER, George D., Captain, Columbus, Ga.
SEGERSON, Edward C., 1st Lieut., Memphis, Tenn.
SHAW, Clarence, 1st Lieut., Chattanooga, Tenn.
SMAHA, Tofey G., 1st Lieut., Griffin, Ga.
SMITH, John E., 1st Lieut., Fitzgerald, Ga.
SMITH, Virgil D., 1st Lieut., Leeds, Ala.
SYKES, Charlie L., 1st Lieut., Pilot Mountain, N. C.
WACHTEL, Leo M., Jr., 1st Lieut., Jacksonville, Fla.
WEEKS, Richard B., Captain, Augusta, Ga.
WELLING, Arthur W., 1st Lieut., Newberry, S. C.
WILLIAMS, Miles W., 1st Lieut., Gamilla, Ga.
WORTHY, William S., 1st Lieut., Carrollton, Ga.
YEOMANS, James W., 1st Lieut., Barnesville, Ga.
ZIRKLE, John G., 1st Lieut., Greeneville, Tenn.

Relieved from Duty

The following officers previously reported have been relieved from duty, or the orders have been revoked:

JORDAN, William K., 1st Lieut., Milledgeville, Ga.
MUSE, William S., 1st Lieut., Knoxville, Tenn.

SEVENTH CORPS AREA

Ordered to Camp Joseph T. Robinson

The following medical reserve corps officers had been ordered to extended active duty by the Commanding General, Seventh Corps Area, up to December 13, with permanent station at Camp Joseph T. Robinson, Arkansas. The Seventh Corps Area comprises the states of North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas and Wyoming.

BROWN, James Matthews, 1st Lieut., Caledonia, Minn.
BURTON, Frank Marques, 1st Lieut., Hot Springs National Park, Ark.
CLARK, Henry Bannister, Jr., Captain, St. Paul.
DALEY, Lyle Miner, Major, Hamilton, Mo.
DEVINE, John Leo, Jr., 1st Lieut., Minot, N. D.
DUNLAP, Richard Leonidas, 1st Lieut., Lawrence, Kan.

HAIGLER, James Pierre, 1st Lieut., Pittsburg, Kan.
HARRISON, Glenn Ellwood, Captain, Mason City, Iowa.
HENDERSON, Robert Wesley, Captain, Bismarck, N. D.
HOBBS, Russell Eugene, 1st Lieut., Wichita, Kan.
HOGAN, Paul Wilbur, Captain, Waukon, Iowa.
JOHNSTON, Charles Harlan, Captain, Des Moines, Iowa.
LENTZ, Harold Calvin, 1st Lieut., Neosho, Mo.
MASON, James Anders, 1st Lieut., International Falls, Minn.
MEYER, Alvin John, Captain, Lake City, Minn.
NEWKIRK, William Henry, Captain, Berryville, Ark.
PATTERSON, Harold Loyd, 1st Lieut., Lyons, Kan.
RIEGLMAN, Ralph Harold, 1st Lieut., Des Moines, Iowa.
SCHERLING, Sidney Saul, Captain, Taylors Falls, Minn.
SIEBERT, Norman Clifford, 1st Lieut., Canada, Kan.
STEINLE, George Henry, Captain, Burlington, Iowa.
STERNHILL, Irving, Captain, Mason City, Iowa.
TONEY, William Egbert, 1st Lieut., St. Joseph, Mo.
WEBSTER, LuVerne John, 1st Lieut., Battle Lake, Minn.
WILSON, William Errol, 1st Lieut., Greensburg, Kan.

The following officers are ordered to extended active duty for a period of one year with permanent station at Fort Snelling, Minnesota:

JOHNSON, Christian G., 1st Lieut., Rugby, N. D.
McCANN, Eugene John, Captain, Minneapolis.

The following officer is ordered to extended active duty for a period of one year with permanent station

at Jefferson Barracks, Missouri, by the Commanding General, Seventh Corps Area:

SCHUCK, Carl Alfred, Captain, St. Louis.

The following officer is ordered to extended active duty for a period of one year with permanent station at Fort Meade, South Dakota:

NYQUIST, Roy Henning, Captain, Iroquois, S. D.

EIGHTH CORPS AREA

The following additional medical reserve officers had been ordered to active duty by the Commanding General, Eighth Corps Area, up to December 13. The Eighth Corps Area comprises the states of Colorado, Arizona, New Mexico, Oklahoma and Texas.

AARNI, John C., 1st Lieut., Hayden, Ariz.
BAGGETT, Seldon O., 1st Lieut., Austin, Texas.
BALDRIDGE, Max, 1st Lieut., Bowie, Texas.
BUKOWSKI, Lucian M., Captain, Houston, Texas.
BURNETT, Berry H., Lieut. Col., Englewood, Colo.
CANTRELL, William B., Lieut. Col., Gallup, N. M.
COCHRAN, Joel L., Major, San Antonio, Texas.
COHEN, Mayer, 1st Lieut., Marlin, Texas.
COOLEY, Ben H., Major, Norman, Okla.
DARNELL, Elmer E., Major, Colony, Okla.
DAVIS, Charles Q., Major, Houston, Texas.
DAVIS, James H., Lieut. Col., Fort Worth, Texas.
FULMER, H. Ray, 1st Lieut., Ringling, Okla.
GALLAHER, Frank C., 1st Lieut., Shawnee, Okla.
GEE, Kenneth J., 1st Lieut., Tulsa, Texas.
GWINN, Frank W., Captain, Yuma, Ariz.
HARRELL, Fred S., Captain, Olney, Texas.
HAWKINS, Winfred W., Captain, Waco, Texas.
HOLTZ, Harvey E., 1st Lieut., Dallas, Texas.
JOHNSON, George H., Major, Ardmore, Okla.
KEATING, Peter M., Lieut. Col., San Antonio, Texas.
KINDER, Thurman A., Major, Brownsville, Texas.
LAPAN, Charles H., 1st Lieut., Lamar, Colo.

LEHMANN, Cornelius F., Major, San Antonio, Texas.
LITTELL, George S., Major, Dallas, Texas.
LOWIN, Julian R., 1st Lieut., Redvale, Colo.
LUBBEN, John F., Jr., Major, Dallas, Texas.
MAGID, Morston A., 1st Lieut., Denver.
MILES, John B., Captain, Anadarko, Okla.
MOORE, Isham Seller, 1st Lieut., Ozono, Texas.
MOORE, John D., Major, Fort Worth, Texas.
MURRAY, Edward Cotter, Captain, Ada, Okla.
NICHOLSON, John R., Major, San Antonio, Texas.
OLIVER, Claudius H., Lieut. Col., Douglas, Ariz.
PACE, Bedford F., 1st Lieut., Noderland, Texas.
POLLACK, Simon, 1st Lieut., Tulsa, Okla.
PRIDAY, Codric, Major, Corpus Christi, Texas.
PROSSER, Moorman P., 1st Lieut., Norman, Okla.
RAGAN, Tillman A., 1st Lieut., Fairfax, Okla.
ROBERTS, Charles J., 1st Lieut., Enid, Okla.
SAKS, Harry S., Captain, Denver.
SANFORD, Herbert M., 1st Lieut., Perryton, Texas.
SHAW, Dwight B., Captain, Pueblo, Colo.
SHORBE, Howard B., 1st Lieut., Oklahoma City.
SLAY, Iris J., Major, Fostoria, Texas.
STUARD, Charles G., Jr., 1st Lieut., Tulsa, Okla.
WALKER, Marcellus A., Jr., Captain, Paris, Texas.
WINTER, John W., Captain, San Antonio, Texas.
WOLF, Edward T., Major, Houston, Texas.

Orders Revoked

KERNEK, Paul, 1st Lieut., Oklahoma City.
TURNBOW, William Ray, 1st Lieut., Tulsa, Okla.

NAVAL RESERVE OFFICERS ORDERED TO ACTIVE DUTY

The following additional naval medical reserve officers have been ordered to active duty:

BARNES, Mark H., Lieut., M. C.-V. (S.), New York, Submarine Base, New London, Conn.
EHRlich, Harry, Lieut. (j. g.) M. C.-V. (G.), U. S. N. R., Dispensary, Navy Yard, Brooklyn.
HARRISON, Edward K., Lieut., M. C.-V. (S.), U. S. N. R., Ossining, N. Y., Ossining Hospital, Marine Barracks, Quantico, Va.
HELD, Albert H., Lieut., M. C.-V. (G.), Huntingburg, Ind., Norfolk Naval Hospital, Portsmouth, Va.
HIGGINS, Homer A., Comdr., M. C.-V. (S.), Little Rock, Ark., to Director of Selective Service, Arkansas (Duty as State Medical Adviser).
HOEY, Waldo O., Lieut., M. C.-V. (S.), Providence, R. I., Naval Training Station, Newport, R. I.
HORST, John V., Lieut., M. C.-V. (S.), Upper Arlington, Ohio, Naval Hospital, Great Lakes, Ill.
HOYLE, Christian K. C., Lieut., M. C.-V. (S.), Roanoke, Va., Jefferson Hospital, First Marine Brigade, Fleet Marine Force, Quantico, Va.
KEIGWIN, Charles G., Lieut. (j. g.) M. C.-V. (S.), Evanston, Ill., Naval Reserve Aviation Base, Chicago.

KING, W. Ivan, Lieut. Comdr., M. C.-V. (S.), Dallas, Texas, Hospital, San Diego, Calif.
LETCHER, Charles W., Lieut., M. C.-V. (S.), Wilkes Barre, Pa., Naval Reserve Aviation Base, Philadelphia.
LEVY, Louis K., Jr., Lieut. (j. g.) M. C.-V. (S.), New Orleans, Marine Recruiting Station, New Orleans.
MARCO, David M., Lieut., M. C.-V. (S.), Amarillo, Texas, Naval Air Station, Jacksonville, Fla.
MILLER, Wade Hampton, Lieut. Comdr., M. C.-V. (G.), Kansas City, Mo., Naval Reserve Aviation Base, Kansas City, Kan.
MORRISON, Arlo A., Lieut., M. C.-V. (S.), Santa Barbara, Calif., Naval Hospital, San Diego, Calif.
OARD, Harry Clifford, Lieut. Comdr., M. C.-V. (S.), Jamaica, N. Y., Norfolk Naval Hospital, Portsmouth, Va.
SIMPSON, George W., Jr., Lieut., M. C.-V. (S.), Norfolk, Va., Navy Yard Dispensary, Norfolk Navy Yard, Portsmouth, Va.
WALVOORD, James H., Lieut. Comdr., M. C.-V. (S.), Hollis, N. Y., Norfolk Naval Hospital, Portsmouth, Va.
WRIGHT, Orville M., Lieut. (j. g.) M. C.-V. (G.), Nashville, Tenn., Vanderbilt University Hospital, Navy Recruiting Station, Nashville, Tenn.

AVIATION MEDICAL EXAMINERS

The following medical officers of the U. S. Army, who have been under instruction at the School of Aviation Medicine, Randolph Field, Texas, graduated as Aviation Medical Examiners, October 19:

ANDERSON, John L., Captain, M. Res., Barksdale Field, La.
BARRETT, Robert S., 1st Lieut., M. C. R., Langley Field, Va.
BILOTTA, Laurence A., Captain, M. C., Army Medical Center, Washington, D. C.
BLOUNT, Robert H., Captain, M. C., Vancouver Barracks, Wash.
BROOKS, Robert H., M. C. R., Kelly Field, Texas.
CALAWAY, William, Captain, M. C., Army Medical Center, Washington, D. C.
CAMERON, Richard R., Captain, M. C., Army Medical Center, Washington, D. C.
CROUCH, Thomas H., 1st Lieut., M. C., Fort Bliss, Texas.
DIAMOND, Max M., M. C. R., Kelly Field, Texas.
GARCIA, Charles Todd, 1st Lieut., M. C. R., Puerto Rican Department.
HARGAN, William S., Captain, M. C., Fort Benning, Ga.
JENKINS, Raymond T., Captain, M. C., Fort Bragg, N. C.

JOHNSON, Hensley S., Captain, M. C., AC Advanced Flying School, San Angelo, Texas.
KELLY, Frederick C., Captain, M. C., AC Advanced Flying School, San Angelo, Texas.
LELICH, Bronko P., 1st Lieut., M. C., Army Medical Center, Washington, D. C.
LLOYD, Harvey L., Captain, M. C., Army Medical Center, Washington, D. C.
MARKS, Maurice Isaac, 1st Lieut., M. C. R., Maxwell Field, Ala.
MATTHEWS, John L., Captain, M. C., Texas National Guard, San Antonio, Texas.
McDONOUGH, Joseph F., 1st Lieut., M. C. R., Moffett Field, Calif.
McGREGG, George D., Captain, M. C., AC Basic Flying School, Montgomery, Ala.
MORRIS, Charles K., Captain, M. C., Westover Field, Chicopee Falls, Mass.
PERRI, Frank A., 1st Lieut., Langley, Field, Va.
PIGFORD, Charles Alfred, Captain, M. Res., Maxwell Field, Ala.
SHAFFER, Frank J., 1st Lieut., M. C., AC Troops, Savannah, Ga.
SOLTZ, Gustav D., 1st Lieut., M. C. R., Lowry Field, Denver.
STAFFORD, Charles A., 1st Lieut., M. C., Fort Douglas, Utah.
TALBOT, John M., Captain, M. C., Hamilton Field, Calif.
TOWNER, Alonzo A., Jr., Captain, M. C., Fort George Wright, Wash.
WAINER, Amos S., 1st Lieut., Randolph Field, Texas.

ORGANIZATION SECTION

OFFICIAL NOTES

THE CLEVELAND SESSION

Special Exhibits on Fractures and on Lame Backs

The Committee on Scientific Exhibit announces that there will be two special exhibits at the Cleveland session as follows:

Special Exhibit on Fractures.—Presented by a committee composed of Dr. Kellogg Speed, Chicago, chairman; Dr. Frank D. Dickson, Kansas City, Mo., and Dr. Walter Estell Lee, Philadelphia.

Special Exhibit on Lame Backs.—Presented under the auspices of a committee composed of Dr. Frank R. Ober, Boston, chairman; Dr. Carl E. Badgley, Ann Arbor, Mich.; Dr. J. Archer O'Reilly, St. Louis; Dr. Arthur Steindler, Iowa City, and Dr. Philip D. Wilson, New York.

Applications for space for other exhibits close on Jan. 20, 1941. Blanks may be obtained from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

RADIO BROADCASTS

"Doctors at Work" is the title of the sixth annual series of dramatized radio programs being presented by the American Medical Association and the National Broadcasting Company.

The series opened Wednesday, November 13, and will run for thirty consecutive weeks, closing with a broadcast from the A. M. A. meeting at Cleveland on June 4, 1941. The program is scheduled for 10:30 p. m. eastern standard time (9:30 central, 8:30 mountain, 7:30 Pacific time) over the Blue network, other N. B. C. stations and Canadian stations.

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio

network and local stations, and no revenue is derived from the programs. Therefore, local stations may or may not take the programs, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

Some radio stations may be unable to broadcast the program at the regular scheduled time and may transcribe and broadcast it at another hour or even on another day. It is advisable, therefore, to verify the time by reference to local newspapers or by telephoning the local Blue network stations.

The programs will dramatize what modern medicine offers the individual in the way of opportunities for better health and the more successful treatment of disease. Incidental to this main theme the programs will explain the characteristics of the different fields of modern medicine and its specialties.

Descriptive posters for local distribution may be had gratis from the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Program titles will be announced weekly in *THE JOURNAL* and monthly in *Hygeia*, The Health Magazine.

Tickets are available for each broadcast. Address the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago. Tickets are free, but a stamped self-addressed envelop should accompany requests.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

January 1.* Otorhinolaryngologist.
January 8. Your Eyes.
January 12. Best Foot Forward.

* This program only will be broadcast one hour and a half earlier than the regular scheduled time in order to clear the network for international broadcasts later in the evening.

WOMAN'S AUXILIARY

National Board Meeting

The stated meeting of the board of directors of the Woman's Auxiliary to the American Medical Association was held, November 29, in Chicago with Mrs. V. E. Holcombe, Charleston, W. Va., the president, presiding.

The four past national presidents who attended were Mrs. Samuel Clark Red, Houston, Texas; Mrs. Rogers N. Herbert, Nashville, Tenn.; Mrs. Robert E. Fitzgerald, Milwaukee, and Mrs. Charles C. Tomlinson, Omaha. Mrs. R. E. Mosiman, Seattle, president-elect, was present, as were also ten members of the executive committee, ten chairmen of standing committees, sixteen state presidents, three state presidents-elect and four regional chairmen. Mr. Frank V. Cargill and Dr. W. W. Bauer were guest speakers, answering questions on *Hygeia* and the A. M. A. radio hour series respectively. Four members of the Advisory Council, Drs. Booth, Bloss, Fenton and Sensenich and Dr. Van Etten, President of the American Medical Association, were guests at lunch. Mrs. Red, first president of the national auxiliary, was guest of honor. Twelve visiting Chicago auxiliary women were also present. The nominating committee was elected and plans were made for the convention in Cleveland, June 1-6, 1941.

Preceding the board meeting, the advisory council was host at the A. M. A. headquarters at a luncheon for the executive committee of the auxiliary. Many enjoyed the opportunity of making a tour of the American Medical Association Building.

California

The auxiliary to the Los Angeles County Medical Association gave a formal dinner-dance November 5 at the Wilshire Bowl for the benefit of the Los Angeles Physicians' Aid Association. A sum of \$500 was realized from the affair, which, it is planned, will be held annually for the same purpose.

Nebraska

The auxiliary to the Lancaster County Medical Society met, Nov. 4, 1940, at the home of Mrs. Wesley Becker. Mrs. A. D. Brown, state president, was a guest and spoke briefly. Mr. M. C. Smith, executive secretary to the Nebraska State Medical Association, talked to the group on medical legislation.

The Adams County Medical Association and its woman's auxiliary met for a dinner meeting at Ingleside, Nov. 6, 1940. Judge Blackledge, the after-dinner speaker, spoke on "The Story of a Witness." The auxiliary is knitting and crocheting for the Red Cross.

The officers of the six-county medical auxiliary were entertained at a luncheon, October 9, at the Perkins Hotel in David City by Mrs. R. C. Gramlich, president. Mrs. A. D. Brown was an honor guest.

Utah

The Woman's Auxiliary to the Salt Lake County Medical Society met in October at the Newhouse Hotel to discuss "Where Go the Boats," and folk lore of all nations. The afternoon was in charge of Mrs. Walter H. Horton, who, in rhyme, introduced the speakers—Mrs. L. A. Stevenson, Mrs. Richard P. Middleton, Mrs. J. Albert Peterson and Mrs. Francis Boyer. Music featuring Indian and Chinese melodies was played by Mrs. Claude L. Shields. Preceding the regular program a pageant, "Hygeia, Goddess of Health," was given by Mrs. Alfred Clawson, Mrs. Raymond Maw and Mrs. Roland Merrill. Tea and a social hour followed the program.

A business meeting of the Utah County auxiliary was held in October at the home of Mrs. Garland Pace in Provo. Mrs. Wilford Woolf, the president, was in charge of the meeting.

The state board, with Mrs. J. R. Morrell of Ogden presiding, held its meeting in October at the Lion House in Salt Lake City. Plans for the year were outlined.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Personal.—Dr. Edward F. Ellis, Fayetteville, has given his medical library of more than 1,000 volumes to the University of Arkansas School of Medicine, Little Rock.—Dr. John L. Ruff, formerly of St. Paul, has been appointed medical director for Crawford, Franklin and Logan counties, succeeding Dr. Albert S. J. Clarke, Ozark, who plans to enter the school of public health at Harvard University, it is reported.—Dr. James M. Lemons, Pine Bluff, has given his medical library to the Jefferson County Medical Society.

CALIFORNIA

Outbreak of Influenza.—A report has been received concerning the recent epidemic of influenza in San Francisco. According to Dr. Jacob C. Geiger, city health officer, the disease appeared in mild form. The incubation period ranged from three to five days and was even as short as twenty-four hours. It is estimated that 10 per cent of the population in the city was affected.

Society News.—The Los Angeles Society of Neurology and Psychiatry and the Endocrine Study Group held a joint meeting, December 18; a symposium on the hypothalamus was presented by Drs. Cyril B. Courville, Samuel J. Glass, Frederick S. Modern and Arthur R. Timme.—The speakers before the Los Angeles Society of Ophthalmology and Otolaryngology, December 23, included Drs. Daniel E. Ziskin on "Destructive Ophthalmia Associated with Atypical Erythema Multiforme," and Warren A. Wilson, "Congenital Lenticule Fibroblastic Membranes."

CONNECTICUT

Fatality from Tularemia.—The death of a man at the Newington Hospital, East Hampton, December 14, from tularemia is said to be the first from this cause in the state, according to the *New York Times*. The man cut his finger while preparing a rabbit, which he had killed on a hunting trip November 23. Five days later he showed symptoms. He became unconscious and was taken to the hospital December 9.

Course on Industrial Medicine.—The Connecticut Clinical Congress has arranged a course on industrial medicine for physicians of the state to begin January 9 at Yale University School of Medicine, New Haven. The first subject will be "Ventilation in Industry." Other subjects to be discussed are:

- January 16, Pulmonary Diseases Due to Dust.
- January 23, Infections in Industry.
- January 30, Dermatitis and Carcinogenic Substances.
- February 6, Poisoning by Benzol—Other Industrial Solvents.
- February 13, Carbon Monoxide Poisoning and Other Irritant Gases.
- February 20, Lead Poisoning.
- February 27, Poisoning by Other Heavy Metals.
- March 6, Caisson Disease and Diseases Due to Changes in Atmospheric Pressure.
- March 13, Cardiac Diseases in Industry.
- March 20, Adequate Nutrition for the Industrial Worker.
- March 27, Medical and Health Services in Industry.
- April 3, Preventive Industrial Medicine.
- April 10, Legal Aspects of Occupational Diseases.

Dr. Louis H. Nahum, New Haven, is chairman of the program committee of the Clinical Congress of the state medical society.

DELAWARE

Society News.—Dr. George E. Bennett, Baltimore, discussed problems of knee joint surgery before the New Castle County Medical Society, November 19, in Wilmington.—A symposium on glaucoma is being presented by the section of ophthalmology and otolaryngology of the Delaware Academy of Medicine, Wilmington, in three meetings, November 19, December 17 and January 21. Included among the speakers are Drs. William O. LaMotte, Richard R. Tybout, Gerald O. Poole, Norman L. Cutler and William R. Hazzard.

DISTRICT OF COLUMBIA

Personal.—Dr. Rex E. Buxton, Boston, has been appointed director of the Washington Institute of Mental Hygiene, succeeding Dr. Paul J. Ewerhardt, resigned.—Dr. James A. Gannon has been appointed a member of the District board of education, newspapers report.

Society News.—Dr. Jesse G. M. Bullowa, New York, addressed a meeting of the medical and dental officers of the navy on duty in the District and vicinity, November 4, on "The Appropriate Therapy of the Pneumonias."—Dr. Everts A. Graham, St. Louis, addressed the monthly meeting of Army Medical Department officers in Washington and vicinity at the Army Medical Center, November 18, on "Surgery of the Chest." Dr. Henry K. Mohler, Philadelphia, spoke, October 14, on "Use of Sulfanilamide and Its Associated Compounds."

GEORGIA

Industrial Hygiene Service.—The Georgia Department of Public Health has established an industrial hygiene service as a part of the division of preventable diseases to meet the increasing needs of advisory service to industries in the protection and promotion of the health of industrial workers. The service, consisting of medical and engineering advisory assistance, will soon be available to all types of industries.

Pediatric Meeting.—The Georgia Pediatric Society met at the Biltmore Hotel, Atlanta, December 12. The speakers included:

- Dr. Lee Edward Farr, Wilmington, Del., Prognostic Value of Renal Function Tests in Nephritis: Role of Diet in the Therapy of Nephritis.
- Dr. Samuel Z. Levine, New York, The Handicaps of Prematurity and How to Meet Them: Water and the Growing Organism.
- Dr. Edward F. Bland, Boston, Manifestations of Rheumatic Fever in Childhood: Course of Rheumatic Heart Disease in Childhood and Adolescence.

Personal.—Dr. Joseph A. Johnson, Greensboro, resigned as head of the Greene County health unit, effective November 1, to accept a similar position at Toccoa in charge of the unit including Stephens, Habersham and Rabun counties.—Dr. James A. Thrash, health officer of Columbus and of Muscogee County, has been granted leave of absence until June 1941 to take special studies in health work at the University of North Carolina School of Medicine, Chapel Hill.—Dr. Roy L. Johnson, Douglas, has resigned as health commissioner in Coffee County to enter private practice.—Dr. Robert V. Schultz, New York, has been named director of public health education for the state department of health.

ILLINOIS

Society News.—Dr. Adolph L. Sahs, Iowa City, discussed "The Common Neuroses" before the Adams County Medical Society, November 11.—A symposium on diseases of the biliary tract was presented before the Coles-Cumberland County Medical Society in Mattoon, November 7, by Drs. Karl A. Meyer and Manuel E. Lichtenstein, Chicago.—Dr. Oscar F. Schultz, Evanston, was elected president of the Illinois Society of Pathologists at its annual meeting, December 7; Dr. Israel Davidsohn, Chicago, is the secretary.

Chicago

Society News.—Dr. George J. Garceau, Indianapolis, addressed the Chicago Orthopedic Society, December 13, on "Treatment of Scoliosis" and Dr. Fremont A. Chandler, "Aseptic Necrosis of the Head of the Femur."—The Chicago Pediatric Society was addressed, December 17, by Dr. Alvin C. Rambar, among others, on "The Opsono-Cytophagic Test in Pertussis Inoculation."

Study Group Named in Honor of Dr. Sonnenschein.—A medical history study group has been organized at the Michael Reese Hospital and named in honor of the late Dr. Robert Sonnenschein. The first meeting of the new group, December 11, was addressed by Dr. Reuben Friedman, assistant professor of dermatology and syphilology, Temple University School of Medicine, Philadelphia, whose subject was "Acarus Scabiei—The Story of a Twelve-Hundred Years' Search for the Obvious."

Mr. Bacon Retires as Superintendent of Presbyterian Hospital.—After more than forty years' service at Presbyterian Hospital, Asa S. Bacon will retire as superintendent, January 1. He will be succeeded by J. Dewey Lutes, who has been superintendent of Ravenswood Hospital for the last nine and one-half years. Mr. Bacon is a trustee of the American Hospital Association and has been its treasurer for thirty-five years, with the exception of one year when he served as president. In recognition of his long service, the association last February named its reference library at 18 East Division Street the Asa S. Bacon Library.

INDIANA

Personal.—Dr. George R. Douglas, Valparaiso, has been appointed health officer of Porter County, filling the vacancy caused by the death of Dr. Herman O. Seipel.

District Meeting.—Dr. Harry A. Towsley, Ann Arbor, Mich., recently addressed the Seventh District Medical Society in Franklin on "Diagnosis and Treatment of Acute Contagious Diseases." He also showed a colored motion picture on the acute stages of exanthemas.

Society News.—A symposium on arthritis was conducted before the Madison County Medical Society, November 18, in Anderson by Drs. Francis M. Williams, Frederick B. Wishard, Aubrey W. Elsten and Paul T. Lamey. All are from Anderson. —Dr. Norman E. Freeman, Philadelphia, discussed "Peripheral Circulatory Failure: Its Prevention and Treatment" before the Indianapolis Medical Society November 26. —Dr. Thomas M. Conley, Kokomo, discussed "Brain Tumors in Children" before the Howard County Medical Society in Kokomo, November 1.

LOUISIANA

Carville Patients Honor Perry Burgess.—The Patients' Federation and the American Legion Post of Carville, comprised entirely of leper patients, gave a reception in honor of Mr. Perry Burgess, president of the Leonard Wood Memorial, New York, and author of the book "Who Walk Alone," at the Marine Hospital, Carville, November 27. The welcome to Mr. Burgess was for the work he has been doing in behalf of leper patients. "Who Walk Alone" is the story of an American soldier who served in the Spanish-American War in the Philippines, and who became a leper many years after he had returned home.

MAINE

Society News.—Dr. Eugene E. O'Donnell discussed problems of intestinal surgery before the Portland Medical Club recently. —The York County Medical Association was addressed in Biddeford, October 9, by Dr. William J. Brickley, Boston, medical examiner for Suffolk County, on "Cause and Manner of the *Squalus* Deaths."

MARYLAND

Regulations for Occupational Diseases.—At a meeting, October 14, the Maryland State Board of Health adopted regulations for the control and prevention of occupational diseases, effective January 1. The Baltimore City Department of Health and the division of industrial hygiene of the United States Public Health Service cooperated in the formulation of the regulations. Regulation 1 is as follows:

No persons, firm, corporation or other employer shall use or permit to be used in the conduct of his business, manufacturing establishment or other place of employment, any process, material or method of working known to have an adverse effect on health, unless arrangements have been made to maintain the occupational environment in such a manner that injury to health shall not result.

Regulation 2 pertains to concentration limits and reads:

Exposures to dusts, fumes, mists, vapors, gases, or any materials that may affect health shall be kept below the following concentration limits:

Material	Concentration
Benzene (Benzol)	75 parts per million
Carbon tetrachloride	100 parts per million
Carbon monoxide	100 parts per million
Chlorine	1 part per million
Chromic acid	0.1 mg. per cubic meter

MASSACHUSETTS

Society News.—The New England Pathological Society was addressed, November 21, by Dr. Harry S. N. Greene, Princeton, N. J., on "Development of Autonomy in Spontaneous Rabbit Tumors." —Dr. Otto J. Hermann, Boston, discussed "Convalescent Care of Fractures" before the New England Society of Physical Medicine, November 21, in Boston. —The Essex South District Medical Society was addressed, December 4, by Dr. Walter Bauer, Boston, on "Diagnosis and Treatment of the Commoner Arthritides." Dr. James C. White, Boston, will address the society in Hathorne, January 8, on "Visceral Pain and Its Relief." —Dr. Thomas M. Rivers, New York, delivered a Robert Dawson Evans Memorial Lecture in the Evans Memorial Auditorium, Massachusetts Memorial Hospitals, Boston, November 19, on "Elementary Bodies of Vaccine."

MICHIGAN

Changes in Health Officers.—Dr. Lorin E. Kerr, Toledo, has been appointed director of the Iron County health department, succeeding Dr. Thomas E. Camper, who is on leave of absence for graduate study at the University of Michigan, it is reported. —Dr. Buell H. Van Leuven, Petoskey, has been named health officer of Menominee County to succeed Dr.

Clifford C. Corkill, who is studying at the Johns Hopkins University School of Hygiene and Public Health, Baltimore.

Society News.—Dr. Robert E. Lee, Chicago, discussed "Ambulatory Treatment of Varicosities and Associated Pathology" before the Muskegon County Medical Society, November 15. —Dr. Winthrop Morgan Phelps, Baltimore, addressed the Calhoun County Medical Society, November 18, on "The Spastic Child" and Dr. Robert B. Malcolm, Chicago, November 12, "Surgical-Pathological Conditions of the Neck." —Dr. Richard H. Freyberg, Ann Arbor, addressed the Washtenaw County Medical Society, Ann Arbor, November 12, on "Treatment of Chronic Arthritis." —The medical section of the Wayne County Medical Society was addressed, November 11, by Dr. Joseph T. Wearn, Cleveland, on "Changes in the Coronary Circulation Resulting from Normal and Abnormal Processes." —Among others, Dr. Frederick F. Yonkman, Detroit, addressed the Detroit Physiological Society, November 14, on "Depression of the Sympathetic Nervous System."

Annual Clinic of Highland Park Physicians' Club.—The fifteenth annual clinic of the Highland Park Physicians' Club was conducted at the Highland Park General Hospital, November 6. Included among the speakers were:

Dr. Andrew C. Ivy, Chicago, Medical Treatment of Gallbladder Disease.
Dr. Plinn F. Morse, Detroit, Pathology of Gallbladder Disease and Its Effect on the Human Body.
Dr. Willis D. Gatch, Indianapolis, Surgical Treatment of Gallbladder Disease.
Dr. Frederick A. Collier, Ann Arbor, Shock: Differential Diagnosis and Treatment.
Mr. P. A. Pranion, Detroit, Demonstration of Falling Drop Method.
Dr. Marion A. Blankenhorn, Cincinnati, Recent Advances in Vitamin Therapy.
Dr. Russell L. Haden, Cleveland, Rheumatoid Arthritis—Etiology and Treatment.
Dr. David S. Hillis, Chicago, Diagnosis of Disproportion Between Head and Pelvis.

MINNESOTA

The Bell Lecture.—Dr. Leroy U. Gardner, director, Saranac Laboratory for the Study of Tuberculosis, Saranac Lake, N. Y., delivered the seventh annual John W. Bell Lecture before the Hennepin County Medical Society, Minneapolis, December 2. His subject was "Manifestations of Tuberculosis in the Silicotic Patient."

MISSOURI

Personal.—Members of the executive faculty and the library staff of Washington University School of Medicine, St. Louis, recently observed the twenty-fifth anniversary of Miss Ella B. Lawrence as librarian. A silver bowl was presented to Miss Lawrence. —Dr. Lawrence T. Post, who recently retired as editor of the *American Journal of Ophthalmology*, was guest of honor at a dinner given by the St. Louis Ophthalmic Society at the University Club, St. Louis, November 27.

Society News.—A symposium on pneumonia was conducted before the Jackson County Medical Society, Kansas City, November 26, by Drs. John Aull, Harvey P. Boughnau and Lindsay S. Milne. All are of Kansas City. —Dr. Milton C. Winternitz, New Haven, Conn., addressed the Kansas City Academy of Medicine, November 15, on "Experimental Studies on Arteriosclerosis." —The Kansas City Society of Obstetrics and Gynecology was addressed, November 7, by Clarence W. Sondern, Ph.D., on "Newer Information on Estrogenic Substances." —Dr. Robert M. Isenberger addressed the Kansas City Urological Society, November 7, on "Pharmacology of the Urinary Antiseptics." —A symposium on infantile paralysis was presented before the Buchanan County Medical Society, St. Joseph, November 6; the speakers were Drs. William J. Hunt, Walter Roger Moore and Jacob Kulowski. All are from St. Joseph.

MONTANA

Personal.—Dr. John H. Garberson, Miles City, was recently elected governor of district 112 of the Rotary International.

Another Medical Supplement.—An eight page Health Section was published on October 13 by the *Sunday Democrat-News*, Lewiston, in cooperation with the Fergus County Medical Society.

NEBRASKA

Society News.—Dr. Newell C. Gilbert, Chicago, addressed the Omaha-Douglas County Medical Society, Omaha, November 12, on "Reflex Variations in Coronary Blood Flow." Dr. Claude F. Dixon, Rochester, Minn., was the speaker December 10 on "Surgical Diseases of the Colon." —The Five County and Madison Six County medical societies held a joint meeting in Norfolk, November 19. A symposium on fractures was presented by Drs. Robert D. Schrock and James W. Martin, Omaha, and George A. Haslam, Fremont.

NEW YORK

Institute on Radiology at Syracuse.—An institute on radiology will be held at the Syracuse University College of Medicine, Syracuse, January 18, under the sponsorship of the Central New York Roentgen Ray Society, the Medical Society of the State of New York, the division of cancer control of the New York State Department of Health and the medical college. Speakers in the afternoon will be:

Edith H. Quimby, associate physicist, Memorial Hospital, New York, Physics of Radiation for the Radiologist.

Dr. Merrill C. Sosman, Boston, Roentgenologic Aspects of Brain Tumors, Diagnosis and Treatment.

Dr. Ursus V. Portmann, Cleveland, Indications and Results of Roentgen Therapy.

Dr. Fred W. Stewart, New York, Radiosensitivity of Tumors.

Dr. Stafford L. Warren, Rochester, The Cyclotron.

At a dinner meeting Dr. Roscoe R. Spencer, assistant chief of the National Cancer Institute, U. S. Public Health Service, Bethesda, Md., will be the speaker.

New York City

Lecture on Digitalis.—Dr. Harry Gold, assistant professor of pharmacology, Cornell University Medical College, will deliver a lecture at New York Medical College, January 17, under the auspices of the Omicron chapter of Phi Delta Epsilon. Dr. Gold's subject will be "Some Recent Studies on Digitalis."

Photographic Contest for Social Hygiene Program.—The Society for the Study of Syphilis, in cooperation with the Metropolitan Camera Club Council and the U. S. Public Health Service, is sponsoring a competition for photographs to be used in public health education in venereal disease control. Merchandise prizes will be awarded for the ten best entries. For rules, the society may be addressed at Room 329, 125 Worth Street.

Personal.—Dr. Jack Masur, assistant director of Montefiore Hospital, has been appointed director of Lebanon Hospital. He will assume the position January 1, succeeding Mr. George E. Halpern, who is retiring after twenty-three years of service. Dr. Edwin L. Demuth will succeed Dr. Masur at Montefiore Hospital.—Dr. Charles F. W. Bove, for many years on the staff of the American Hospital of Paris, recently joined the staff of Gotham Hospital. Dr. Bove, a native of New York, went to France during World War I.

Dr. Humpstone Honored.—Dr. O. Paul Humpstone, chief of the department of obstetrics and gynecology at the Methodist Hospital, Brooklyn, was honored at a dinner marking his retirement from that position, December 6. Dr. Humpstone, a graduate of Columbia University College of Physicians and Surgeons in 1899, served his internship at the Methodist Hospital and has been associated with the hospital ever since. He is also professor of clinical obstetrics and gynecology at Long Island College of Medicine. At the dinner Bishop Francis J. McConnell of the Methodist Church paid tribute to Dr. Humpstone and Ralph Emerson Davis, pastor of St. Mark's Methodist Church and a member of the hospital's board of managers, presented to the guest of honor a leather-bound testimonial which bestowed on him the title of director emeritus of the division of obstetrics and gynecology.

NORTH CAROLINA

Portrait of Dr. Manning.—The alumni association of the University of North Carolina School of Medicine, Chapel Hill, recently presented to the university a portrait of Dr. Isaac H. Manning, Kenan professor emeritus of physiology and former dean of the school. Dr. William Raney Stanford, Durham, a former student under Dr. Manning, made the presentation and President Frank P. Graham accepted for the university.

Society News.—Dr. William S. Justice, Asheville, discussed "Use and Abuse of Vitamin K" before the Buncombe County Medical Society, Asheville, November 18.—Dr. James E. Bullitt, Chapel Hill, was elected president of the North Carolina Pathological Society at its annual meeting in Charlotte, November 19, and Dr. Coy C. Carpenter, Wake Forest, reelected secretary. Dr. Charles F. Geschickter, Baltimore, was the guest speaker on "Benign and Malignant Breast Tumors."

OHIO

Morris Memorial Lecture.—The fifth annual Roger S. Morris Memorial Lecture was presented at the University of Cincinnati College of Medicine, December 11, by Bradley M. Patten, Ph.D., professor of anatomy, University of Michigan Medical School, Ann Arbor. His subject was "Age Changes

in Embryonic Heart Action as Recorded in Micro-Moving Pictures and Studied Electrocardiographically."

Physicians Elected to Legislative Bodies.—Dr. Frederick C. Smith, Marion, was reelected to Congress from the eighth Ohio district, the *Ohio State Medical Journal* reports. Drs. Henry T. Phillips, Athens, and Everett LeFever, Glouster, were reelected to the state general assembly and Drs. George G. Hunter and Forrest R. Stewart, Ironton, were elected to the state senate and house of representatives, respectively.

Veteran Physicians Honored.—Dr. Norval A. Hamilton, Franklin, was guest of honor recently at a testimonial dinner attended by physicians and other friends of the Miami Valley area to celebrate his completion of fifty years in practice. Dr. Martin H. Fischer, Cincinnati, made the principal address. Dr. Hamilton was presented with a watch.—Gold plaques were presented to three physicians who have practiced fifty years or more by the Highland County Medical Society at a meeting in Hillsboro, November 6. They were Drs. John A. Mercer, Greenfield; Thomas W. Roberds, Belfast, and J. Barrett Kleckner, Lynchburg.—Six Medina County physicians who have practiced twenty-five or more years in the county were honor guests at a meeting of the Medina County Medical Society in Medina, November 14. They were Drs. Hiram P. H. Robinson, Medina; Harry Streett and Walter H. Scudder, Litchfield; Ernest L. Crum, Lodi; Edwin J. Kooztz and Robert L. Johnson, Wadsworth.

OREGON

Meeting of Specialists.—The North Pacific Society of Neurology and Psychiatry held a meeting at the University of Oregon Medical School, Portland, November 9. The morning program included the following speakers: Drs. John L. Haskins, Portland, "Statistics on Admissions, Cost and Attendant Ratio of Private and State Mental Hospitals in the Northwest"; De Witt C. Burkes, Portland, "Familial Cerebellar Degeneration," and Robert H. Southcombe, Spokane, Wash., "Pyknolepsy." In the afternoon a neurologic symposium was presented as follows: Drs. John E. Raaf, Portland, "Lindau's Disease"; Charles O. Sturdevant and Thomas D. Robertson, Portland, "Multiple Sclerosis"; Laurence Selling, Portland, "Syringomyelia," and Charles P. Larson, Tacoma, Wash., and Vinton D. Sneed, Portland, "Amaurotic Familial Idiocy (Tay-Sachs Disease)." George Bernard Noble, Ph.D., professor of political science, Reed College, Portland, was the dinner speaker.

PENNSYLVANIA

Society News.—Drs. John Royal Moore and William Edward Chamberlain, Philadelphia, addressed the Locomotion County Medical Society, Williamsport, December 13, on "Delayed Reduction of Fractures," discussing surgical and clinical aspects and roentgenologic aspects, respectively.—Dr. Richard J. Behan, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, December 5, on "Diagnosis and Control of Cancer."—Dr. Percy S. Pelouze, Philadelphia, addressed the Delaware County Medical Society, Chester, December 12, on "Urinary Bladder in Health and Disease."—Dr. Stephen A. Forbes, State College, addressed the Centre County Medical Society, Bellefonte, December 12, on "Backache, Its Causes and Treatment."—Dr. Murray B. Ferderber, Pittsburgh, discussed "The Selection of Heat in Physical Medicine" before the Mercer County Medical Society, Farrell, December 11.—Dr. William H. Guy, Pittsburgh, addressed the Blair County Medical Society at Altoona in November on "Dermatologic Manifestations of Syphilis."

Philadelphia

Annual Gross Lecture.—Dr. Virgil H. Moon, professor of pathology, Jefferson Medical College, delivered the annual Gross Lecture of the Pathological Society of Philadelphia, December 12, on "Pathology and Vascular Dynamics of Shock."

Society News.—At a meeting of the Eastern Pennsylvania Chapter of the Society of American Bacteriologists, November 26, the speakers were Dr. Esmond R. Long and Agnes B. Vogt on "Relation of Sex to the Course of Experimental Tuberculosis in Mice"; Dr. Max B. Lurie, "Relationship of Hereditary Constitution and Immunologic Factors in Resistance to Tuberculosis"; Florence B. Seibert, Ph.D., and Mr. John T. Glenn, Glenolden, Pa., "Improvements in the Preparation of Purified Protein Derivative Tuberculin," and Dr. Joseph D. Aronson, with Dr. Robert M. Saylor and Erna I. Parr, U. S. Indian Medical Service, "Incidence of Coccidioides Immitis Infection in Some Parts of the United States."

SOUTH DAKOTA

Personal.—Dr. Alpha J. Campbell, recently of Los Angeles, has been appointed chief medical officer at the Veterans' Administration Facility, Hot Springs.

Public Health Meeting.—The annual meeting of the South Dakota Public Health Association was held in Huron, October 28, with Dr. Gaylord W. Anderson, Minneapolis, as the guest speaker. Dr. Anderson spoke on "Tuberculosis Control Through Epidemiologic Investigation" and "Role of the Part-Time Health Officer."

TENNESSEE

Regional Meeting.—The semiannual meeting of the Middle Tennessee Medical Association was held in Franklin, November 21. Among other speakers were Drs. Frank J. Runyon, Clarksville, on "The Therapy of Malaria, Especially Stressing an Improved Therapeutic Test"; Tinsley R. Harrison, Nashville, "Some Clinical Aspects of Pain in the Chest"; Roscoe C. Gaw, Gainesboro, "Upper Respiratory Tract Infections and Their Influence on the Pulmonary System," and Granderson Hearn Bradley, Nashville, "Vitamins B and K in Pediatrics."

Dr. Blalock Honored for Research.—Dr. Alfred Blalock, professor of surgery, Vanderbilt University School of Medicine, Nashville, received the research medal of the Southern Medical Association at the annual meeting in Louisville, Ky., in November. The award was made in recognition of Dr. Blalock's research on circulation of the blood in cases of shock. Dr. Blalock graduated from Johns Hopkins University School of Medicine, Baltimore, in 1922 and went to Vanderbilt for a residency in 1925, becoming assistant professor of surgery in 1927 and professor in 1937.

WISCONSIN

The Bardeen Lecture.—Dr. Ernest E. Irons, Chicago, delivered the annual Charles R. Bardeen Memorial Lecture at the University of Wisconsin Medical School, Madison, December 6, on "Aspiration Pneumonia: Pathology-Bacteriology-Symptoms." The lecture is sponsored by the Phi Chi fraternity.

In Memory of Dr. Dearholt.—An all day meeting in memory of the late Dr. Hoyt E. Dearholt, Milwaukee, for many years executive secretary of the Wisconsin Anti-Tuberculosis Association, was held at the University of Wisconsin Medical School, Madison, November 26, under the auspices of the tuberculosis association and the university. Dr. James Burns Amberson Jr., New York, the guest speaker, discussed "Diagnosis of Pulmonary Tuberculosis" and "Principles of Treatment of Tuberculosis."

Society News.—Dr. Tracy J. Putnam, New York, addressed the University of Wisconsin Medical Society, Madison, November 22, on "Physiology and Treatment of Paralysis Agitans and Athetosis."—Drs. Malcolm G. Gillespie and Edward L. Tuohy, Duluth, Minn., addressed a recent meeting of the Polk County Medical Society, Webster, on "Vitamin K in Cases of Liver Depletion With and Without Jaundice" and gout.—Drs. Robert B. Osgood, Boston, and Albert A. Mertz, Decatur, Ill., addressed the Milwaukee Society of Clinical Surgery, November 26, on "Backgrounds of Bone and Joint Surgery" and "Advance in Treatment of Fractures of the Hip" respectively.—Dr. Everett D. Plass, Iowa City, addressed the Medical Society of Milwaukee County, Milwaukee, November 8, on "Newer Advances in the General Field of Obstetrics."

GENERAL

The Bombing of England's Hospitals.—Despite the German claim that their bombing is confined to military objectives, the fact is, the Manchester *Guardian Weekly* says, that numerous nonmilitary objectives, including hospitals, churches, world famous buildings, stores, clubs, newspaper offices and other nonmilitary objectives have been bombed. The following are some of the hospitals that have been hit:

London Hospital	Swiss Relief Center
Queen Mary's Hospital	Great Ormond Street Hospital
St. Bath's Medical School	St. Dunstan's Hospital
St. Thomas's Hospital	Tunbridge Wells Hospital
Chatter House Clinic	Royal Hospital (Chelsea)
Ford's Hospital	Royal College of Surgeons
Coventry Hospital	

Honored for Aid to China.—Medals of honor for distinguished service to China were presented, October 25, to eleven members of the board of directors of the American Bureau for Medical Aid to China by Dr. Fu-Ching Yen, formerly national health administrator of China. Those so honored included Drs. James B. Murphy, Farn B. Chu and George B. Wallace, New York; Homer W. Smith, S.C., professor of

physiology, New York University; Dr. George Morris Piersol, Philadelphia, and Dr. Robert R. Hannon, Albany, N. Y. Certificates accompanying the medals bore the signature of Chiang Kai-Shek and the official seal of the Executive Yuan and paid tribute to the work of the recipients for relief of China's war sufferers.

Census of Medical Manufactures.—The U. S. Bureau of the Census has released additional figures showing in detail the production of surgical supplies and equipment, orthopedic appliances and kindred products and a separate report on rubber products for use in hospitals and by the medical profession. An earlier report appeared in *THE JOURNAL*, November 23, page 1817. The figures are for the year 1939.

Manufacturing establishments devoted mainly to the production of surgical supplies and equipment, orthopedic appliances and kindred products produced goods during 1939 valued at the factory at 3 per cent more than those produced during 1937.

During 1939 the 360 establishments operating in this industry turned out merchandise estimated by the producers at \$79,398,442. In 1937 the 323 establishments then included valued the output for that year at \$77,068,094.

The 360 factories also spent nearly \$5,000,000 less for materials, supplies, fuel, purchased electric energy and contract work in 1939 than did the 323 establishments two years before: \$40,296,584 in 1939 compared with \$45,030,602 in 1937, a difference of 10.5 per cent. With production up and cost down, the value added by manufacture was 22.1 per cent higher in 1939 than in 1937. The value added by manufacture is the value of products after the cost of materials, supplies, fuel and the like has been subtracted. This total amounted to \$39,101,858 last year, compared with \$32,037,492 in 1937.

Of the \$79,398,442 worth of products manufactured by the 360 factories last year, \$66,108,877 represented the value of surgical supplies and equipment not elsewhere classified, and orthopedic appliances alone. The difference between the first and the last quoted figure includes \$223,582 received for contract work and \$13,065,983 worth of products classified in other industries. In all instances the 1939 total was higher than that for 1937, when a breakdown of the production of the 323 plants in the industry revealed that \$65,328,236 represented the value of surgical supplies and equipment and orthopedic appliances made, \$158,444 the value of contract work and \$11,581,414 the value of secondary products.

An incomplete report on the value of surgical supplies and equipment and orthopedic appliances produced in other industries last year puts the figure at \$5,571,103. In 1937 this figure, when finally computed, was \$5,788,762. Complete figures on this item will not be available until the final report for 1939 is issued.

The factory value of crutches, fracture appliances, elastic hosiery, abdominal supporters, braces, arch supporters, absorbent cotton and medicated plasters made during 1939 was higher than the value of those produced in 1937, while the output of artificial limbs, stumpsocks, surgical belts, suspensories, trusses, surgical gut strings, nonmedicated adhesive plasters, bandages and surgical gauze and dressings had a higher factory value in 1937 than last year.

Though the 1939 figures on sanitary napkins were not all in at the time the preliminary report was sent to the printer, the incomplete figures disclose that it was the biggest single item turned out by the industry last year. The value of the sanitary napkins so far reported is \$12,984,464. In 1937 factories reported the production of this item at \$14,418,756. That year, too, it was the major item turned out by the industry.

For the first time hospital, surgical and other sterilizers have been reported separately. Last year's output of these goods was valued at \$1,153,680 by the manufacturers' estimates.

All figures in the report are preliminary and in several cases incomplete. These figures are subject to revision before being published in final form. Plants that had a production of less than \$5,000 last year are not included in Census of Manufactures reports.

Rubber products having a value at the factory of at least three million dollars were manufactured last year. Production of hospital sheeting was valued at \$1,639,519, a substantial gain over the 1937 figure of \$1,072,522. These prices cover quantities of 3,857,247 square yards in 1939, compared with 2,982,123 square yards in 1937.

Surgeons' gloves produced last year had a value of \$1,099,605, numbering 851,581 dozen pairs. No separate figures were obtained for this category in 1937.

In addition, an undetermined amount of medical and surgical hard rubber products are included in the 1939 total of \$7,037,325 for medical and druggists' rubber sundries other than water bottles, fountain syringes, nipples and pacifiers.

BUENOS AIRES

(From Our Regular Correspondent)

Oct. 24, 1940.

Fifth Pan American Congress for Tuberculosis

The fifth Pan American Congress for Tuberculosis, in which eleven Spanish American countries with 150 delegates participated, was held in Buenos Aires and Córdoba, October 13-17. The United States was represented by Dr. Henry C. Sweany. The Oficina Sanitaria Panamericana in Washington was represented by Dr. Henson as observer. The congress was held under the auspices of the Latin-American Union of Societies for Tuberculosis, in which Argentina, Bolivia, Brazil, Colombia, Chile, Cuba, Mexico, Paraguay, Peru, Uruguay and Venezuela hold membership. Dr. Gumersindo Sayago, professor in Córdoba, presided. Argentina was represented at the opening meeting by Dr. R. S. Castillo, acting president of the Argentine Republic. The sessions were formally opened by Dr. G. Rothe, minister of the Department of Justice and Public Instruction. Dr. G. Sayago, president of the congress, linked his remarks in his opening speech to one of the chief subjects of discussion, the indexes of tuberculization in South America. He pointed out that the reports submitted by the individual countries, members of the congress, clearly revealed the presence of a common epidemiologic problem, in that tuberculosis had spread to a great extent in a uniform way. Similar geographic, racial, economic and social problems prevailed. The environmental factors of tuberculosis in Spanish American countries differed greatly from those of other countries with an older civilization. In these, general sanitation was more advanced and tuberculization had had a wider sweep. South American countries, on the other hand, rather resembled countries in which tuberculosis appeared as a new disease. Only the large South American cities presented an epidemiology analogous to that of other countries. In spite of the declining mortality rate, tuberculosis still constituted a social problem of the greatest significance. Beds available for tuberculous patients in South America were insufficient and increased the hazards of infection in the homes. Even where conditions were most favorable there was only one bed for from three to four patients who died of the disease. No effective tuberculosis control was possible without the isolation of infected persons.

The first deliberative session was held on the second day with the "Indexes of Tuberculization in South America" as the leading subject. Alejandro A. Raimondi and Julio Palacio, members of the Argentine delegation, defined the term index as representing the percentage of persons of a certain age, collectivity, race or religion who had been tubercularized. The average index for Argentina was as follows: from 0 to 6 years 44.5 per cent, from 7 to 14 years 54.1 per cent, from 15 to 20 years 67.3 per cent and above 20 years 72.3 per cent. Female incidence preponderated until the fourteenth year. The examination of 84,854 males and females at all age levels showed that 64.8 per cent presented sensitivity. Primary infection, formerly contracted more often in childhood, now appeared more often in early adulthood, the index fluctuating in Argentina between 26 and 84.2 per cent (the latter for Buenos Aires). The index for children of school age in Buenos Aires varied from 75.53 per cent in central locations to 32 in one of the suburbs. Everywhere the incidence was much lower in rural districts. Epidemiologically, tuberculous infections in Argentina show different stages of evolution regionally. In Jujuy, in the northern part of the state, a high index of 71.9 per cent prevailed together with a high mortality rate of 23.9 per 10,000 inhabitants. In the large cities, while the index was high, the mortality rate was on the decline.

In Bolivia, the epidemiologic index for the cities is high and is related to their economic condition. Because of the great frequency of anergy, vaccination with BCG is extensively recommended. In Brazil, owing to limited funds, the index remains high in comparison with European countries, which showed a decline during the last fifteen years at the ages below 20 years. Surveys in Brazil are not complete. Chile is still in the stage of massive tuberculization. The percentage of the allergic at the age of 6 years is high and the index at age 15 is 80 per cent. In Cuba the infection index, based on about 54,000 persons examined in Havana, was as high as 74 per cent in persons regarded as normal, and the morbidity rate 4 per cent; whereas it amounted to 11.7 per cent in sections of the population in which there was contact with the tuberculous. In Peru, children between 1 month and 16 years of age living in an infected environment and with tuberculin-positive reactions gave an index of 56.9 per cent, whereas in Lima, the capital of Peru, the index for children between 6 and 16 years in an apparently normal environment amounted to 65.3 per cent. In Uruguay great interest was exhibited in creating careful case lists and in the usual tuberculin tests. Sensitivity to the Mantoux test in relation to Pirquet's test was as follows: From the sixth year on the Mantoux test added 20 per cent of allergic cases to those discovered by the Pirquet tests if the positive results of the Pirquet test did not exceed 75 per cent. The formulation of international classification standards was recommended for the purpose of describing roentgenologic observations. At present great difficulties exist for the evaluation of allergy. It was also recommended that the next Pan American Congress for Tuberculosis request its member countries to conduct a systematic examination of the whole population. This would undoubtedly lower the index. In Venezuela, tuberculosis represents one of the most serious problems of public health. The mortality rate in the cities from tuberculosis varies from 210 to 470, with an average of 321 per hundred thousand inhabitants. In certain cities the mortality ranges from 12.3 to 23.16 per cent. An active pulmonary infection rate of 1.52 per cent was found in children of school age and a 3.58 per cent rate in pregnant women. The morbidity incidence is high, especially in the first years of life. It recedes between the tenth and the nineteenth year but rises again and attains its peak at age 30. No noteworthy differences in this respect were found between white and Negro persons.

HEREDITY

The subject for the second day was Heredity and Infection. Dr. A. Cetrángolo, representing the Argentine delegation, pointed out that, since immunity was not hereditary, it was difficult to understand how heredity could possess any decisive influence in evolving a human type capable of greater resistance to tuberculosis. The tuberculosis-resistant type does not represent the transmission of specific immunity but is a selective phenomenon. If the factor of heredity were as significant as assumed, the population of Europe, which had been in contact with tuberculosis for so many centuries, would be completely immune by this time. Moreover, the mortality rate for tuberculosis would not mount with economic crises. In infections, intensive bacillary invasion in persons with low nonspecific resistance evokes great hypersensitivity and low relative immunity and induces caseous processes; on the other hand, infections with low bacillary concentration provoke processes of a weakened hypersensitivity but with high relative immunity resulting in mitigated processes and allergy without morbidity. A connection exists between heredity and infection. Both factors cooperate with other factors and either promote or repel bacillary invasion. During the evolution of an infection, either grave or mild conditions will prevail in accordance with the concentration of bacilli. Heredity has only genotypic significance and is unable to bestow a specifically greater resistance.

The sessions of the third day of the congress were held in the city of Córdoba. The faculty of medicine of Córdoba has clinical opportunities because of the many sanatoriums situated in the clinically suitable province of the same name. Dr. Sofanor Novillo Corvalán, rector of the University of Córdoba, pointed out that since the first Pan American Congress held in Córdoba in 1927 the mortality incidence for tuberculosis in the city had decreased from 28.1 per 10,000 inhabitants to 17.9 in 1935, representing a reduction of 40 per cent, attributed to the systematic control of the disease. In behalf of the committee of organization, Raimondi stressed the necessity of cooperation of all South American countries. Several of these countries had recently showed an increase of tuberculosis and thus presented new problems to be solved. Population sections, immune until then, needed to be vaccinated with BCG. The European war constitutes a cause of anxiety also for the peoples of South America, because in the years to come the same factors would make themselves felt, such as a social imbalance, impoverishment and economic difficulties of all kinds. These factors either singly or collectively could lead to the spread of tuberculosis.

EXTRAPULMONARY TUBERCULOSIS

The paper, presented by Dr. Raúl A. Vaccarezza and José B. Gómez, was based on clinical and roentgenologic examinations of 420 male and female patients with extrapulmonary tuberculosis varying in age and degree of infection. Lung modifications were found in 90.2 per cent, a detailed analysis of which was presented to the congress. Extrapulmonary tuberculosis, they concluded, does not generally behave like isolated chronic tuberculosis of other body organs but tends, simultaneously or concomitantly, to become established in the systems of other organs, including the lung. Extrapulmonary tuberculosis and pulmonary tuberculosis are not mutually exclusive or antagonistic. On the contrary, the two increasingly combine. If the etiology of a disease is obscure and at the same time hematogenic modifications of the lung are observed, tuberculosis should be suspected. Patients with extrapulmonary tuberculosis ought not to be consigned to general hospital wards but be given special wards. So-called isolated chronic tuberculosis affecting an organ is not to be regarded as a local lesion but as a general condition capable of infecting other organs.

The Brazilian delegates were of the opinion that extrapulmonary cases generally represented metastasis of pulmonary lesions which spread by way of the blood stream. The Chilean delegates were in accord with this point of view and pointed out that 61 per cent of all cases of extrapulmonary tuberculosis were associated with active pulmonary lesions, 59 per cent of which represented reinfections and 2 per cent primary infections. In from 50 to 55 per cent the pulmonary pictures accompanying extrapulmonary tuberculosis show advanced and extensive lesions. Among them the mixed type predominates (31 per cent), with the diffused miliary type next in frequency (16 per cent). The presence, type and evolution of pulmonary lesions determine the prognosis of the extrapulmonary forms. Surgical wards should be established in hospitals for tuberculous diseases, closely cooperating with specialists in the field of tuberculosis. The age level at which extrapulmonary tuberculosis appears and its evolution create problems of invalidism and social dependence that make such centers desirable. Paraguay's delegates presented an extensive statistical tabulation of extrapulmonary tuberculosis occurring in their country. Peru's delegates called attention to the fact that extrapulmonary tuberculosis had not received sufficient attention in the fight on tuberculosis. Pure extrapulmonary forms, free from active pulmonary infections, amount to 24 per cent. Isolated extrapulmonary tuberculosis has mostly a renal or osteo-articular site. If pulmonary infections and extrapulmonary lesions coexist, the latter are generally of a secondary nature, indicating the collapse of allergy. The Uruguay delegates, who

had studied extrapulmonary tuberculosis only in adults, observed fifty-seven cases (6.69 per cent) of extrapulmonary infection out of 852 cases of pulmonary tuberculosis. This is in accord with general experience. They concluded from the rarity of extrapulmonary lesions and the clinical and morphologic pictures that diffusion is hematogenic. Investigations made in Venezuela confirmed these observations.

Habana was chosen as the meeting place of the next congress, to convene in 1943. Dr. Juan J. Castillo, a Cuban delegate, was named as chairman. Subjects for discussion planned are the Value of BCG Vaccination, Initial Stages of Tuberculous Infections and Systematization of the Therapy in Pulmonary Cavities.

Marriages

LIEUTENANT COMMANDER JOHN MATTHEW BACHULUS, M.C., U. S. Navy, to Mrs. Grace Adams East of Oakland, Calif., October 21.

JAMES BENJAMIN SHULER, Shenandoah, Va., to Miss Mary Catherine McCarthy of Butte, Mont., in Waikiki, Hawaii, August 31.

LOUIS WILLIAMS LADD JR., Cleveland, to Miss Barbara Schutz of San Antonio, Texas, at Mount Washington, Md., September 7.

RICHARD E. EDMONDSON, Hartford, Conn., to Miss Virginia Gholson of Clarksville, Tenn., in Nashville, Tenn., in September.

GRACE HUMPHREYS HOOD, Fort Worth, Texas, to Mr. Derwood Morton of Arlington in Dallas, September 12.

KENDRICK McCULLOUGH, Yonkers, N. Y., to DR. MARGARET WHITTAKER LAWRENCE of New York, November 8.

RUTH F. WOLCOTT, Spirit Lake, Iowa, to Mr. Otto William Fischer of Okoboji at Clear Lake, September 29.

BEN ALLEN DREIBOOT, Jacksonville, Fla., to Miss Norma Elizabeth Thomas in Augusta, Ga., October 7.

MILBURN H. QUERNA, Spokane, Wash., to Miss Patty Paxton of Springdale, in Lewiston, Idaho, October 3.

EUGENE J. MAIRE, Vail, Iowa, to Miss Betty Jane Van Ackeren of Humphrey, Neb., September 17.

BROWN McILVAINE DOBYNS, Jacksonville, Ill., to Miss Meredith Davis of Evanston in September.

OWEN M. CARROLL, New Castle, Ky., to Elizabeth Giles Thomas at Mount Sterling in October.

SHEPARD A. BURROUGHS to Miss Eleanor Mahan Hubbard, both of Ashtabula, Ohio, in October.

EINAR A. LUNDBURG, Hartford, Conn., to Miss Dorothy A. Oldfield in Burlington, Vt., June 15.

THOMAS BRICE MITCHELL to Miss Sara Elizabeth Tyson, both of Shelby, N. C., November 3.

JACK GRAHAM WEBB, Richmond, Va., to Miss Frances Skelton at Louisville, Ky., September 21.

H. FREDERICK KEIBER to Miss Marie Julian Hollan, both of Staten Island, N. Y., August 30.

ROBERT A. COEN to Miss Margaret Kernan, both of Ingleside, Neb., at Hastings, August 28.

WILLIAM J. SCHNUTE, Ann Arbor, Mich., to Miss Doris Davis of Lansing, June 29.

WENTWORTH L. OSTEEN to Miss Kate Elaine Goodson, both of Augusta, Ga., August 3.

ROBERT H. WAHL to Miss Florence Edith Hagedorn, both of Dayton, Ohio, in October.

LAD J. KUCERA, Lonsdale, Minn., to Miss Ethel Irene Benson in Omaha, September 28.

GILBERT D. KEIL, Toledo, Ohio, to Miss Carol Hoesman of Woodville in October.

LAWRENCE E. HURT to Miss Louise Conlee, both of Lexington, Ky., October 28.

LEONARD KLEIN to Miss Evelyn Rotkowitz, both of New York, November 9.

J. SAMUEL BLAIR, Gastonia, N. C., to Miss Mary Gwynne Fewell in October.

JORGE A. TRELLES to Miss Conchita Gonzalez, both of Tampa, Fla., in October.

Deaths

Carl Lucas Alsberg, Berkeley, Calif.; Columbia University College of Physicians and Surgeons, New York, 1900; assistant in physiologic chemistry, Harvard Medical School, Boston, from 1902 to 1905 and instructor of biochemistry from 1905 to 1908; chemical biologist, bureau of plant industry, United States Department of Agriculture from 1908 to 1912, and chief, bureau of chemistry, from 1912 to 1921; director of the food research institute, Stanford University, from 1921 to 1937 and, since 1937 consultant; dean of graduate studies at Stanford University from 1927 to 1933; since 1937 director of the Giannini Foundation of Agricultural Economics at the University of California; during the World War was chief chemist for the department of agriculture in the War Industries Board; member of the advisory committee on land utilization of the National Resources Planning Board; member of the American Society of Biological Chemists, of which he was a former president, American Chemical Society, for which he was a councilor and associate editor of its journal, and the Washington Academy of Sciences, of which he was a former president; aged 63; died, October 31, in the Alta Bates Hospital of pneumonia.

John Augustus Hartwell, New York; Yale University School of Medicine, New Haven, Conn., 1892; professor of clinical surgery emeritus at Cornell University Medical College, where he was for many years associate professor of surgery and professor of clinical surgery; president of the New York Academy of Medicine from 1929 to 1932 and director from 1934 to 1938; was an associate director of the American Society for the Control of Cancer; member of the Medical Society of the State of New York, the American Surgical Association and the Society of Clinical Surgery; fellow of the American College of Surgeons; served during the World War; consulting surgeon, Bellevue, Reconstruction, Presbyterian, Memorial and Lincoln hospitals, New York, Lawrence Hospital, Bronxville, and United Hospital, Port Chester; aged 71; died, November 30, in Oakdale, N. Y., of pulmonary embolism.

Henry Hurd Rusby, Sarasota, Fla.; University of the City of New York Medical Department, 1885; member of the Medical Society of New Jersey; professor of botany, physiology and materia medica, College of Pharmacy, Columbia University, New York, from 1888 to 1930 and dean from 1904 to 1930; professor of materia medica, University and Bellevue Hospital Medical College, New York, from 1897 to 1902; president of the American Pharmaceutical Association, 1909-1910; pharmacognosist in Bureau of Chemistry, United States Department of Agriculture, from 1912 to 1917; was awarded the Remington Medal of the American Pharmaceutical Association in 1923; author of numerous books; aged 85; died, November 18, of intestinal obstruction.

Joseph Nelson Davis ☉ Twin Falls, Idaho; Kansas Medical College, Medical Department of Washburn College, Topeka, 1907; served as secretary-treasurer of the Idaho State Medical Association from 1922 to 1931, when he was made president-elect, from 1935 to 1938 councilor and in 1938 again elected secretary-treasurer, serving until this year, when he asked to be relieved; served during the World War; on the staff of the Twin Falls County General Hospital; state chairman for the Committee on Medical Preparedness of the American Medical Association; aged 58; died, November 5, of injuries received in an automobile accident.

Frank Eliot West, Brooklyn; Long Island College Hospital, Brooklyn, 1876; professor of materia medica and therapeutics and clinical medicine at his alma mater from 1886 to 1921 and since 1921 emeritus professor of therapeutics and clinical medicine; member of the Medical Society of the State of New York; censor in 1878, vice president in 1890, president in 1891 and trustee from 1892 to 1902 of the Kings County Medical Society; served at various times and in various capacities on the staffs of the Kings County Hospital, Long Island College Hospital and the Brooklyn Hospital; aged 90; died, November 21.

Willard D. Duckworth, New Rochelle, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York; 1909; member of the American Roentgen Ray Society and the Radiological Society of North America; at one time assistant professor of roentgenology at the New York Post-Graduate Medical School, Columbia University; aged 57; on the staffs of the New Rochelle (N. Y.) Hospital, Tarrytown (N. Y.) Hos-

pital, Grasslands Hospital, Valhalla, and the White Plains (N. Y.) Hospital, where he died, November 11, of cerebral hemorrhage.

Frank Newton Irwin, White Plains, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; member of the Medical Society of the State of New York; adjunct professor of ophthalmology at the New York Post Graduate Hospital and Medical School from 1902 to 1907; consulting ophthalmologist, Manhattan Eye, Ear and Throat Hospital, New York; New York Hospital, Westchester Division, White Plains Hospital, St. Agne Hospital, Westchester Division, St. John's Riverside Hospital, Yonkers; aged 75; died, November 11.

Leonard Knight Graves, Elmhurst, N. Y.; Columbian University Medical Department, Washington, D. C., 1885; Bellevue Hospital Medical College, New York, 1887; member of the Medical Society of the State of New York; veteran of the Spanish-American and World wars; formerly an inspector in the New York Health Department; for many years on the staff of the New York Eye and Ear Infirmary, New York; aged 84; died, November 12, in the Veterans Administration Facility, New York.

David Sturges Fairchild Jr. ♂ Colonel, United States Army, retired, New York; Drake University Medical Department, Des Moines, 1897; veteran of the Spanish-American and World wars; was commissioned a lieutenant colonel in the medical corps of the regular army in 1920 and in 1930 a colonel; retired in 1935 for disability in line of duty; fellow of the American College of Surgeons; aged 69; died in November at Waynesboro, Va., of injuries received in an automobile accident.

Daniel Warwick Harmon, ♂ Colonel, M. C., United States Army, Hot Springs National Park, Ark.; University of Virginia Department of Medicine, Charlottesville, 1903; fellow of the American College of Surgeons; commissioned a first lieutenant in the medical corps of the army in 1909, a lieutenant colonel in 1929 and colonel in 1935; served during the World War; was commanding officer of the Army and Navy General Hospital; aged 60; died, November 8, of heart disease.

John King Freeman Ⓢ Louisville, Ky.; University of Louisville Medical Department, 1894; at one time adjunct professor of abdominal surgery and gynecology at his alma mater; past president of the Jefferson County Medical Society; veteran of the Spanish-American and World wars; aged 73; for many years on the staff of the SS. Mary and Elizabeth Hospital, where he died, November 6, of hypertrophy of the prostate, uremia and coronary sclerosis.

Edwin Charles Ebert ♂ Commander, United States Navy, Long Beach, Calif.; Marquette University School of Medicine, Milwaukee, 1916; was commissioned an assistant surgeon in the Medical Corps of the United States Navy in 1917, lieutenant in 1920, lieutenant commander in 1925 and commander in 1935; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; aged 50; died, November 4.

Joseph Thomas Buxton ♂ Newport News, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; member of the House of Delegates of the American Medical Association in 1920, 1922 and 1924; member of the Southern Surgical Association; fellow of the American College of Surgeons; surgeon in chief of the Elizabeth Buxton Hospital; aged 64; died, November 5, of coronary thrombosis and arteriosclerosis.

Joseph Augustus Crisler ♂ Memphis, Tenn.; Memphis Hospital Medical College, 1890; past president of the Shelby County Medical Society; member of the Southern Surgical Association and the Southern Society of Clinical Surgeons; fellow of the American College of Surgeons; aged 72; died, November 18, of cerebral hemorrhage.

Nov. 18, of cerebral hemorrhage.

Jay Harvey Bacon @ Peoria, Ill.; Johns Hopkins University School of Medicine, Baltimore, 1904; member of the Clinical Orthopedic Society; fellow of the American College of Surgeons; served during the World War; on the staff of the Methodist Hospital; formerly on the staff of the Proctor Hospital; aged 63; died, November 18, of arteriosclerotic heart disease.

James Andrew Brown * Commander, U. S. Navy, San Diego, Calif.; Ohio State University College of Medicine, Columbus, 1917; appointed assistant surgeon in 1917, promoted to the rank of lieutenant in 1920, lieutenant commander in 1925 and commander in 1935; aged 47; died, November 16, in the United States Naval Hospital of chronic myocarditis and nephritis.

Frank Taylor Andrews, Pasadena, Calif.; Chicago Medical College, 1884; member of the Illinois State Medical Society; professor emeritus of gynecology at his alma mater, now the Northwestern University Medical School; fellow of the American College of Surgeons; aged 82; died, November 7, of arteriosclerosis.

Percy Daniel Hoover ♂ Waynesboro, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; member of the board of trustees of Gettysburg (Pa.) College, and its secretary for many years; on the staff of the Waynesboro Hospital; aged 68; died, November 14.

Joseph Warrington Crawford ♂ North Adams, Mass.; Hahnemann Medical College and Hospital of Philadelphia, 1900; member of the Radiological Society of North America; on the staff of the North Adams Hospital; aged 68; died, November 7, of coronary sclerosis.

Byron Haskin, Theresa, N. Y.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1903; member of the Medical Society of the State of New York; since 1921 health officer of the consolidated health district of Theresa; aged 68; died, November 7.

Clark Wilder Hawley ♂ Chicago; Rush Medical College, Chicago, 1885; an Affiliate Fellow of the American Medical Association; member of the American Academy of Ophthalmology and Otolaryngology; aged 85; died, November 1, in La Grange, Ill.

Frederick Lincoln Emerson ♂ Boston; Boston University School of Medicine, 1892; served in various capacities on the staff of the Massachusetts Memorial Hospitals; for many years on the staff of the Brooks Hospital, Brookline; aged 78; died, November 10.

Siegfried Jackson, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; member of the Illinois State Medical Society; on the staff of the Columbus Hospital; aged 65; died, November 6.

Nellie Calista Flint, Mount Pleasant, Iowa; Hahnemann Medical College and Hospital, Chicago, 1899; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; aged 74; died, November 3.

William Francis Cunningham ♂ New York; Yale University School of Medicine, New Haven, Conn., 1911; served during the World War; on the staff of the Roosevelt Hospital; aged 51; died, November 19, in the Doctor's Hospital.

Joel Herbert Carter, Castleberry, Ala.; University of Alabama School of Medicine, 1910; member of the Medical Association of the State of Alabama; member of the county board of education; aged 59; died in November.

Samuel Scott Blacklock ♂ Hibbing, Minn.; Rush Medical College, Chicago, 1901; fellow of the American College of Surgeons; medical superintendent of the Rood Hospital; aged 66; died, November 12, of coronary thrombosis.

John Joseph Kenney ♂ Providence, R. I.; Dartmouth Medical School, Hanover, N. H., 1908; on the staffs of St. Joseph's, Homeopathic and Lying-In hospitals; aged 56; died, November 7, in the Jane Brown Hospital.

David Wendell Eames, Kecoughtan, Va.; University of the South Medical Department, Sewanee, Tenn., 1908; on the staff of the Veterans Administration Facility; aged 54; died, November 9, of coronary occlusion.

Mary Jardine Evans, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1935; member of the Medical Society of the State of Pennsylvania; aged 44; died, November 6, of tuberculosis.

Jean Girouard, Longueuil, Que., Canada; School of Medicine and Surgery of Montreal, Que., 1879; member of the legislative council from 1899 to 1937; formerly school commissioner; aged 84; died, November 12.

Michael Scott Kearns, Fort Lauderdale, Fla.; St. Louis University School of Medicine, 1926; formerly coroner of Hamilton County, Ohio; served during the World War; aged 40; died, November 14.

Tom Morford Throckmorton, Chariton, Iowa; Jefferson Medical College of Philadelphia, 1877; member of the Iowa State Medical Society; aged 88; died, October 31, in Des Moines of myocarditis.

Thomas Wayne Hancock, Lufkin, Texas; National University of Arts and Sciences Medical Department, St. Louis, 1913; aged 59; was killed, November 4, in an automobile accident.

Robert McKay Greenshields ♂ Romeo, Mich.; Detroit College of Medicine, 1900; served during the World War; aged 67; died, November 15, in the Jennings Hospital, Detroit.

James Henry Maynard ♂ Adair, Iowa; Rush Medical College, Chicago, 1899; past president of the Cass County Medical Society; aged 67; died, October 18, of acute myocarditis.

Gustavo Testa, Waterbury, Conn.; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1902; aged 61; died, October 23, of coronary sclerosis and myocarditis.

John W. Barber, Yokena, Miss.; Kentucky School of Medicine, Louisville, 1884; aged 90; died, November 2, at Edwards of chronic myocarditis, hypertrophy and arteriosclerosis.

Nat Taylor Dulaney Jr., Bristol, Tenn.; Tennessee Medical College, Knoxville, 1893; aged 70; died, November 15, in the King's Mountain Memorial Hospital, Bristol, Va.

Simon Jay Mason, New York; University of Cincinnati College of Medicine, 1936; member of the Medical Society of the State of New York; aged 31; died, November 12.

Albert George Jenner, Milwaukee; University of Pennsylvania Department of Medicine, Philadelphia, 1897; served during the World War; aged 64; died, November 10.

Frederick Hubert Ladd, Canton, N. Y.; Albany (N. Y.) Medical College, 1902; member of the Medical Society of the State of New York; died, October 19.

Taylor Boyd Dixon, Washington, D. C.; Columbian University Medical Department, Washington, 1900; aged 64; died, November 2, of coronary thrombosis.

Robert James Baird, Creston, Ohio; Western Reserve University Medical Department, Cleveland, 1885; aged 87; died, November 3, of cerebral sclerosis.

Timothy Deason, Brachfield, Texas (licensed in Texas under the Act of 1907); aged 84; died, November 5, of heart disease and hypertrophic arthritis.

Harvey Baker Powers, Saranac Lake, N. Y.; University of Pittsburgh School of Medicine, 1920; aged 45; died, October 18, of pulmonary tuberculosis.

Frank Le Count Dowe, New York; New York Homeopathic Medical College and Flower Hospital, New York, 1889; aged 73; died, November 18.

Frank Leonidas Hall, Hannibal, Mo.; Rush Medical College, Chicago, 1887; at one time member of the state legislature; aged 79; died, November 11.

William Wirt Harvey, Boston; Harvard Medical School, Boston, 1898; member of the Massachusetts Medical Society; aged 74; died, November 10.

William Marshall Hinkle, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1891; aged 77; died, November 21.

Albert A. Duclos, Wisconsin Dells, Wis.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1895; aged 79; died, November 4.

Alvin Gustav Berger ♂ Chicago; Eclectic Medical College, Cincinnati, 1916; on the staff of the Grant Hospital; aged 48; died, November 9.

Morris Fallick, New York; Eclectic Medical College of the City of New York, 1905; aged 55; died, November 13, in the Lebanon Hospital.

Samuel Lumpkin Starks, Washington, D. C.; Howard University College of Medicine, Washington, 1920; aged 60; died, October 28.

Irving Edwin Burtnette, Morrice, Mich.; Hahnemann Medical College and Hospital, Chicago, 1898; aged 72; died, November 16.

Robert Tinion Hodgson Jr., Wilkinsburg, Pa.; University of Pittsburgh School of Medicine, 1924; aged 41; died, November 6.

Robert Nelson Buckmaster, Pangburn, Ark.; Gate City Medical College, Dallas, Texas, 1907; aged 71; died, November 17.

Thomas J. Hendrick, Webster, Ky.; Kentucky School of Medicine, Louisville, 1883; aged 80; died, November 6.

Charles J. Ayres, Newbern, Ala.; Medical College of Virginia, Richmond, 1886; aged 70; died, November 12.

Claude Bell, Tuscaloosa, Ala.; Chattanooga (Tenn.) Medical College, 1904; aged 64; died, November 3.

Ernst Theodor Hein, Palouse, Wash.; Baltimore Medical College, 1888; aged 84; died, October 3.

Bureau of Investigation

TWO FRAUDULENT "DIABETES CURES"

The Post Office Department has in the past debarred some "diabetes cures" from the mails, properly taking the stand that anything sold as an immediate or gradual substitute for insulin is an obvious fraud, and particularly dangerous when recommended for self treatment of the condition.

Dr. Samuel E. Edmunds' Concern

From Charleroi and Jeannette, Pa., Samuel E. Edmunds, M.D., and N. Edmunds, described as his wife, put out a mail-order nostrum, "Diabeto." It is said that Dr. Edmunds started the enterprise in 1938, renting a postoffice box at Jeannette, Pa., and doing business under his wife's name for what he called "ethical reasons." This is a timeworn excuse given by renegade physicians who hope to escape notoriety for their quackery by keeping their identities under cover.

"N. Edmunds" advertised that a "New German Remedy" for diabetes was "giving wonderful results" and that a six weeks supply could be had for \$5. Readers who responded received personal letters urging the purchase of Diabeto and advising that by the use of it "many" diabetic patients "get away" from the use of insulin. Also there was a questionnaire to be filled out, on the basis of which the customer was to receive "personal" advice on his case.

These facts were brought out in the memorandum submitted on the matter by Judge Vincent M. Miles, Post Office Solicitor. This document went on to show that persons who returned the questionnaire with the information that they had long been afflicted with sugar diabetes and were under physicians' care involving the use of a restricted diet and the injection of from 15 to 30 units of insulin daily, and who ordered Diabeto on the express basis that it be sent them if it would rid them of diabetes and enable them to discontinue dieting and using insulin, were furnished with Edmunds' nostrum.

Also it was shown that, instead of "personal" advice, Edmunds sent all remitters only stereotyped letters advising them to eat slowly, chew their food well, and purchase laxatives such as citrate of magnesia, Sal Hepatica, Glauber's salt and sodium phosphate. *There were also mimeographed dietary sheets that forbade the use of a wide variety of foods, although Edmunds had led customers to believe that by the use of his treatment they could return to a normal diet. Further, although before they purchased it he had claimed that it would enable them to discontinue taking insulin, after they had undertaken his treatment he advised them to continue using insulin indefinitely.*

Edmunds was quoted as saying that his product was based on a German compound, "Sepdelen," of which he claimed to have heard through an individual who allegedly had recovered from diabetic leg ulcers through the use of Sepdelen. The memorandum brought out that Diabeto was essentially a mixture of four of the sodium salts—the sulfate, tartrate, citrate and phosphate, all common saline laxatives. It also emphasized that it is necessary for a person with diabetes to follow a carefully weighed and balanced diet, with routine injection of insulin, and that there is no drug or combination of drugs known to medical science that is a satisfactory substitute for insulin. It was further pointed out that neither Diabeto nor any other drug nor combination of drugs was known to science as being capable of restoring to normal health the cells of the pancreas gland which have been damaged, atrophied or destroyed. On the contrary, it was shown that a product like Diabeto would injure the patient by keeping him in a state of constant laxation which not only would not control the amount of sugar and other toxins present in his blood but would also debilitate him because of continued loss of minerals and other nutritive substances through the bowels.

As the promoters of the scheme were unable to offer any scientific evidence to support their claims for Diabeto, the solicitor recommended that a fraud order be issued against the names under which they did business—N. Edmunds, Samuel E. Edmunds, M.D. and S. E. Edmunds, M.D. at Charleroi and Jeannette, Pa. It was issued on Dec. 13, 1939.

A Dr. S. E. Edmunds who may have been the person mentioned was listed as "Medical Counselor" on a letterhead of Lee & Company, Philadelphia, that was sent out in August 1939, accompanied by a circular showing that the Lee concern was advertising "Fru-min Salts, formerly German Fruit Salts," also described as "The New Bio-Chemical Therapy for acute, chronic, lingering diseases, treating the CAUSE, composed of 13 remedies, 39 strengths." Although the stuff, from the claims and testimonials cited, purported to be something of a cure-all, the circular declared "We specialize in diabetes." The fact that it was also represented to come from Europe indicates that it may have been identical with or similar to the Sepdelen or Diabeto that has been mentioned.

The circular in question bore the rubber stamp of H. Landgraf, Philadelphia. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for Oct. 27, 1934, carried an article detailing the case of a Post Office fraud order issued against H. Landgraf and his "German Fruit Salts," represented as a veritable cure-all and especially played up for diabetes. The article also brought out that Landgraf was then apparently trying to circumvent the fraud order by putting out a diabetes nostrum under the trade style of "Hilton Chemical Company" at Philadelphia.

Samuel Ernest Edmunds appears in the American Medical Association's records as a graduate of the Atlantic Medical College, Baltimore, in 1910 (the year it became defunct) and as obtaining, in the same year, licenses to practice in Pennsylvania and Maryland, the latter issued by the homeopathic board. He is not shown as a member of his local medical society.

National Diabetic Food Company

Under the foregoing title and also the name "National Diabetic Food Company" a George H. Keys and an R. Randall put out from Kansas City, Mo., "National Diabetic Food" and "National Mineral Ration." The Post Office Department's investigation revealed that these promoters had been in the "diabetes cure" game since 1936, though neither possessed any medical training or experience, nor was any one with such qualifications connected with the company.

Victims were lured by such advertising claims as:

No matter how bad or how long you have suffered, you can now get a treatment that has relieved some of the worst cases we have seen. No drugs or complicated directions. . . .

To persons who "bit" the concern sent printed form letters containing such preposterous misrepresentations as that the causes of diabetes prevail in over two thirds of the American homes and that the remedy lies in National Diabetic Food and its accessory product, National Mineral Ration, through the use of which a person with diabetes would be able to resume a normal diet and gradually quit the use of insulin altogether.

Judge Vincent M. Miles, Solicitor for the Post Office Department, brought out in his memorandum on the case that National Diabetic Food was pulverized and prepared for sale by the promoters in their homes from a weed called saltbush, which they obtained at no cost from farms around Kansas City. Chemical and microscopic analysis in government laboratories showed that it was composed essentially of traces of calcium, iron, phosphate, sodium, potassium and chloride in the form of plant ash.

Similar analysis of National Mineral Ration, the supplementary product which the concern obtained from an Indianapolis concern, revealed that it was essentially composed of minute amounts of epsom salt, calcium, iron, manganese, sodium, potassium, ammonia, carbonate, bicarbonate, sulfate, chloride and sulfur, with traces of iodides, bromides and possibly of copper, zinc and lithium.

The solicitor's memorandum declared that these mixtures, whether used singly or in combination, were absolutely worthless for treating diabetes, a condition due to lack of insulin, a hormone normally secreted by special cells of the pancreas gland which are known as the "islands of Langerhans." The memorandum went on to show that diabetes is characterized by the faulty metabolism of sugars, fats and starches, and the presence of excess sugar, acids and other toxic bodies in the blood and urine; that diabetes is incurable but may be effectively controlled, and blood sugar kept at a normal level by constant use of a

carefully weighed and balanced diet; and that in addition to stringent dietary measures severe cases require routine injections of insulin to compensate for the body deficiency therein.

Further, evidence was presented to show that certain diabetic patients who were treated with saltbush lapsed into diabetic coma both while taking and shortly after they had ceased using it, and that the prolonged use of it had resulted in the deaths of some such patients.

An interesting sidelight on the case was brought out in the revelation that the wife of one of the promoters had died of diabetes while taking these nostrums, which fact he admitted, though he attributed her death to her failure to follow a proper diet. Another feature of the hearing was the defendants' claim that their National Mineral Ration had been analyzed and passed by the Indiana State Board of Health, whereas the Post Office presented information from that board that this claim was untrue.

The conclusion of the solicitor was that there was sufficient evidence that the business was a scheme for obtaining money illegally through the mails, and he recommended the issuance of a fraud order. This was issued on Feb. 1, 1940, against the names National Diabetic Food Co., National Diabetic Food Company, National Diabetik Food Company, Geo. H. Keys, Ps.D., R. Randall, and their officers and agents as such.

The concern, however, like many other outfits that have perpetrated swindles by mail, simply changed its name and continued to do business. In a new memorandum issued by Judge Miles on May 28, 1940, he said of this scheme, in part:

Evidence now before me shows that George H. Keys, in an attempt to evade the effect of the fraud order against the National Diabetic Food Company enterprise, has adopted the assumed and fictitious title of Natur-Food Company, under which name form letters and mimeographed circular matter are being sent through the mails to former customers and others advising them that further purchases of "National Dibetik Food" and "National Minral Ration" may be made from the Natur-Food Company and furnishing a business reply envelope addressed to Natur-Food Company, P. O. Box 2623, Kansas City, Missouri, for that purpose. One of these form letters, on the letterhead of "Tru-Science," reads in part as follows:

Dear Friend: * * *

It seems that a technical error has arisen which is causing the NATIONAL DIBETIK FOOD COMPANY considerable trouble. They believe that, because of the nature of the information that is given out to the public, a large national association is behind this action.

The NATUR-FOOD COMPANY IS HANDLING NATIONAL DIBETIK FOOD, NATIONAL MINRAL RATION AND ELECTREAT MECHANICAL HEART. The same offers, prices and information are available. In ordering, ORDER FROM—

NATUR-FOOD COMPANY

P. O. Box 2623

Kansas City, Mo.

Save this address for future correspondence. MAKE ALL CHECKS AND MONEY ORDERS PAYABLE TO NATUR-FOOD COMPANY. Miss Velma L. Hanson is in charge of the NATUR-FOOD COMPANY and will extend you the same courteous and prompt service that has been the policy of the NATIONAL DIBETIK FOOD COMPANY to give its many customers throughout the nation. The NATUR-FOOD COMPANY will be very pleased to have you order from them. * * *

The evidence further shows that the preparations "National Dibetik Food" and "National Minral Ration" have actually been sold through the mails by Natur-Food Company in response to an inquiry addressed to that concern specifying that the products were desired for use by a diabetic sufferer in place of insulin. Accompanying the preparations was a mimeographed treatise upon the history and alleged value of saltbush (National Dibetik Food) if used continuously, in the treatment of mild, severe, long-standing and gangrenous cases of diabetes. This article bears the signature of T. R. Randall, one of the promoters of the original National Diabetic Food Company enterprise. Attached to this dissertation was a series of mimeographed questions and answers on the subject of the use of saltbush.

The evidence before me shows, and I so find, that this is a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises and is an evasion of the fraud order of February 1, 1940.

While it appears that the name "Tru-Science" is also used in certain instances in such a manner as to imply some connection with the Natur-Food Company, inasmuch as persons solicited are directed to make all checks and money orders for the products purveyed herein payable to the latter concern, it is believed that the extension of the fraud order of February 1, 1940, to cover the name Natur-Food Company only will effectively suppress this scheme.

I therefore recommend that a supplemental fraud order be issued against Natur-Food Company, Natur-Food Co., and their officers and agents as such, at Kansas City, Missouri.

This order was issued on May 28, 1940.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CARDIAC ACTIONS OF QUINIDINE AND DIGITALIS

To the Editor:—While reading the article by Dr. Levy on cardiac arrhythmia in the Sept. 7, 1940, issue of *The Journal* I encountered an old problem of mine. I cannot get a consensus about the comparative actions on the myocardium, auriculoventricular conduction and so on of quinidine and digitalis. In fact, many of the standard textbooks appear to contradict one another in the application of the principles of what these drugs are said to do. The matter has caused considerable argument among my friends and I would appreciate some information on the matter.

M.D., Tennessee.

ANSWER.—Digitalis and quinidine are both valuable remedies for patients with cardiac disease but each has its elected place in cardiac therapy. When each drug is properly used and the limits of its actions are known and its specific indications recognized, much benefit may be expected.

Quinidine, a protoplasmic poison, is known to act directly on the myocardium. It decreases its irritability. It also is known to depress auriculoventricular conduction and to prolong the rate of intraventricular conduction. Although the actual refractory period of auricular muscle may not be prolonged, as pointed out by Love, it is the opinion of Lewis and Drury that the effective refractory period is prolonged by delay of the spread of the impulse through the auricular muscle. It produces vagal depression and occasionally by slowing the rate of the fibrillating auricle it also acts to increase the ventricular rate. It is known that, in 60 per cent of cases of auricular fibrillation, quinidine has been successful in restoring normal sinus rhythm. It is apparently most successful in the cases of fibrillation of short duration or of the paroxysmal type, although it is also occasionally effective in cases of many years' duration. It is least valuable in instances of fibrillation associated with severe cardiac insufficiency and it is here that it has its greatest dangers. It is now believed that it should not be used for patients with marked cardiac disease or auricular fibrillation of many years' duration associated with cardiac enlargement, because of the possibility of producing cardiac standstill. Premature auricular systoles, occurring singly or in short runs, are usually depressed by the use of quinidine. Ventricular extrasystoles, if causing undue symptoms and when not the result of extracardiac mechanisms, may occasionally be quieted with quinidine. The presence of frequent premature ventricular systoles in instances of recent myocardial infarction warrants the use of quinidine to prevent the possible occurrence of ventricular tachycardia and fatal ventricular fibrillation. Occasionally quinidine has been used intravenously in instances of ventricular tachycardia and short runs of ventricular fibrillation, but because of possible peripheral circulatory collapse and drop in blood pressure and also further depression of the conducting tissues it should be used only with great caution. Because of its action in reducing the irritability of the myocardium and in prolonging the intraventricular conduction time, the drug should not be used for patients with marked degrees of block in the conducting system. Because of its peculiar properties as enumerated, it is evident that quinidine has certain definite indications and also contraindications, and these should be fully understood before quinidine is administered.

Digitalis has certain definite known actions on the cardiac mechanism which are well stated in the standard textbooks. It is known definitely to have a selective action on the conduction system, especially the auriculoventricular node, and when used beyond therapeutic dosages it will give rise to bizarre ectopic rhythms and ultimate ventricular fibrillation if not stopped. Together with its stimulating action on the vagus nerve and depression of auriculoventricular conduction, it has been used to slow the ventricular rate and maintain it at a slow rate in auricular fibrillation. Gold and his associates have recently shown that the vagal factor predominates in such instances with moderate digitalization, while the extravagal factor predominates after larger doses. The apparent discrepancy of the action of digitalis in sinus rhythm as contrasted with auricular fibrillation in slowing the ventricular rate is not clearly understood at present. However, the presence of congestive failure, with either sinus rhythm or auricular fibrillation, is an indication for the use of digitalis. In contrast to quinidine, digitalis increases the contractility of the heart. The exact mechanism by which

digitalis does this is not fully explained at present. The one constant effect of the drug is to cause a diminution in cardiac size in normal animals and man and in patients with congestive heart failure. Some investigators have explained this as a consequence of its direct action on the myocardium with varied results. The prevailing theories are that there may be an increase in tone, an increase in systolic force or a decrease in the diastolic length of the individual muscle fibers. Others have attributed its beneficial actions to a peripheral circulatory action by pooling the venous blood in the liver channels, thus decreasing the size of the heart and allowing for more efficient contraction. Discussion of the experimental evidence is not pertinent at this time, but, whatever the exact action may be, digitalis helps to relieve congestive heart failure.

TREATMENT OF TUBERCULOSIS IN NEGROES

To the Editor:—The superintendent of a tuberculosis sanatorium recently stated that collapse therapy (pneumothorax) is inadvisable when the patient is a Negro. He maintained that this is the consensus in leading tuberculosis institutions, citing in particular Bellevue Hospital in New York City. Is belonging to the Negro race now considered a contraindication to collapse therapy in pulmonary tuberculosis? Can you furnish any references on the subject?

M.D., New York.

ANSWER:—At one time it was believed that no treatment was of any avail for Negro patients. This probably was due to the fact that Negroes usually did not report for examination until their disease was too advanced for treatment to be of any benefit. In more recent times, however, there has been much health education work done among Negroes, which has encouraged at least some of them to be examined while apparently in good health. Negro nurses and physicians are doing a great deal of this educational work. Many clinics have been established for those with little or no financial means, which have made examinations readily available. Surveys have been conducted which include examinations of healthy appearing Negroes. These and other activities have resulted in finding tuberculosis in earlier stages when symptoms are present and in the presymptom stage in many cases. Thus, large numbers of Negroes are having tuberculosis detected at a time when it is treatable.

Some workers are of the opinion that the Negro develops a different type of tuberculosis than the Caucasian—a more rapidly progressive type. They are of the opinion that this may be due to lack of immunity; others, however, contend that the Negro does not develop a different type of tuberculosis than the Caucasian but that his exposure often is of such a nature that so many tubercle bacilli are admitted to his body as to produce overwhelming and rapidly progressive disease. In either event, the Negro who does not have hopelessly advanced tuberculosis may have his lesions treated with great success and by the same methods as are employed in the treatment of the Caucasian.

Collapse therapy has been and is being used extensively in the treatment of tuberculosis among Negroes. The procedure of choice is artificial pneumothorax, but when, by reason of adhesions, this cannot be accomplished, surgical procedures, especially extrapleural thoracoplasty, are indicated and have been practiced with remarkable success.

Chadwick, Markoe and Thomas (*Am. Rev. Tuberc.* **28**: 759 [Dec.] 1933) reported the results of treatment of 464 Negroes who had pulmonary tuberculosis. They were all on strict bed rest, and collapse therapy was used in 70 per cent. They divided their patients into light, medium and dark skinned groups. While the results of treatment were a little better in the light skinned group, a higher percentage of improved cases was found in the dark than in the medium group. They concluded that the degree of color is not particularly significant. They produced an excellent record for treatment among these Negroes when one considers that in 90 per cent of the patients the disease had advanced beyond the minimal stage before treatment was instituted.

Brock (*ibid.* **28**: 767 [Dec.] 1933) reported the results of his collapse therapy work on thirty-six tuberculous Negro patients, all of whom were in the advanced stage of the disease when

treatment was begun. Thus he started with a serious handicap. Therefore only 17 per cent were improved or restored to working capacity.

Gaines and Keller (*ibid.* **28**: 779 [Dec.] 1933) also treated Negro patients by collapse therapy and came to the conclusion that the results approximate those obtained in the white race closely enough to reward the physician for his effort and the patient for his cooperation in submitting to this form of treatment. They consider artificial pneumothorax as the procedure of choice, although extrapleural thoracoplasty was used in some cases. With few exceptions they believed that the indications for collapse therapy in the Negro race should be identical with those of other races and the results obtained in their hospital compared favorably with results reported among combined races.

Since these reports were made, large numbers of Negroes have been treated by collapse therapy with excellent results. In Puerto Rico J. Rodriguez Pastor has reported (*Journal-Lancet* **60**: 160 [April] 1940) that ambulatory artificial pneumothorax has been administered to more than 4,000 patients and pneumothorax has been used in large numbers of patients who are hospitalized. Negro patients receive artificial pneumothorax the same as those of other races and apparently with similar results.

Guild, who is director of the Negro program of the National Tuberculosis Association, travels extensively through the South and finds that collapse therapy is being used on Negroes in nearly all of the Southern states.

Therefore the Negro race is not now generally considered a contraindication to collapse therapy in pulmonary tuberculosis. Artificial pneumothorax is doing much not only to control tuberculous lesions in individual patients but also to convert positive sputum to negative and even prevent some patients from becoming contagious.

TOXICITY OF VINYLITE RESINS

To the Editor:—What are the industrial complications such as allergy and toxicity of a product used in dyeing shoes, namely "Vinylite."

Russel G. Means, M.D., Columbus, Ohio.

ANSWER:—"Vinylite" is the trade name for a series of vinyl compounds manufactured by the Carbide and Carbon Chemicals Corporation. This type of plastic may be produced in any color or in translucent and transparent forms. It is suitable for use as articles of personal wear such as belts, suspenders, garters and shoe tops and for dentures, phonograph records and splints and in coating materials. Although no information is available on the use of this type of resin as a shoe dye, patents have been awarded for its use as a coating for textiles. This use involves the addition of ancillary products such as plasticizers, solvents, stabilizers, dyes and inhibitors, which include known skin irritants and sensitizers. Claims have been made that vinyl compounds themselves are nontoxic; however, there still remains the possibility of injury from the other products present. The type of skin injury associated with these resins was described by Dr. Erwin P. Zeisler in *THE JOURNAL*, June 29, page 2540, in an article which refers to dermatitis from garters and wrist watch straps made from vinyl acetate and vinyl chloride. More recently, dermatitis from handling resin-lined tin cans has been reported (Schwartz, Louis, and Russell, J. P.: *Occupational Dermatitis from Handling Resin-Lined Tin Cans*, *THE JOURNAL*, Aug. 10, 1940, p. 448).

SOLUTION OF POSTERIOR PITUITARY FOR HERPES ZOSTER

To the Editor:—What is the rationale for the use of solution of posterior pituitary in the treatment of herpes zoster? I am treating a white man aged 31 with daily injections of 15,000 international units of thiamine hydrochloride. He has herpes zoster involving the ophthalmic division of the trigeminal nerve. The results are apparently good, the lesions crusted after the third injection and the pain has almost disappeared. I have spoken to some men who have used Vitamin B₁ in cases of herpes zoster and they report little success. However, their dosage was lower.

Sidney J. Kohle, M.D., Woodmere, N. Y.

ANSWER:—Somers and Pouppirt (*Herpes Zoster: Some of Its Clinical Aspects*, *California & West. Med.* **42**: 370 [May] 1935) have formulated a theory to explain the action of solution of posterior pituitary and epinephrine in relieving the pain of herpes zoster. Because of the fact that one of the chief changes in the tissues affected in this disease is vasodilatation, they suggest that it is the vasoconstricting action of these drugs that relieves pain in many cases. They differentiate two kinds of pain in zoster: (1) a stabbing, shooting pain, usually intermittent, along the segment or segments involved, usually not sharply localized, and (2) a sharply localized burning, itching or stinging pain at the site of the skin lesions or at the locality at which they are about to appear. Solution of posterior pituitary regularly relieved pain of the second kind

but was not always successful in the neuralgic pain of the first variety, a point in which their experience agrees with that of other writers.

Pillsbury and Fondé (The Treatment of Herpes Zoster, *M. Clin. North America* 20:239 [July] 1936) quote Somers and Pouppirt's theory and agree that it seems to them a reasonable explanation.

Flexner, Chassin and Wright in a recent article (Studies in Herpes Simplex Encephalitis in Rabbits, *J. Infect. Dis.* 66:30 [Jan.-Feb.] 1940) tried vitamin C, sulfanilamide and pitressin in the attempt to control the encephalitis of rabbits. In discussing the possible action of pitressin, they evidently included it in their experiment because of its use in the treatment of herpes zoster and although they apparently had not read Somers and Pouppirt's article they came to the same conclusion, that the drug probably acts by its vasoconstrictive power.

PROBABLE ARTHRITIS OF WRIST

To the Editor:—A girl aged 17 has been playing golf daily during the summer months for the past four years. Last year she developed a pain in the right wrist while playing and it bothered her off and on during the remainder of the summer. Rest for a few days has always relieved the pain. During the winter she practiced on the violin one hour or more daily without experiencing the slightest discomfort in her wrist. On June 1 she began playing golf again and got along well for four or five weeks. The pain then returned and has caused her a great deal of annoyance. The pain seems to be located in the second carpometacarpal, that is, the joint between the second metacarpal and the trapezoid. On examination and questioning I have noted the following points: 1. Pain occurs on pressure on the dorsal surface of the wrist over this joint. 2. Cocking of the wrist at the top of the back swing causes pain in this region. 3. After a round of golf, flexion and extension of the wrist cause pain. 4. Pressure on the palm of the hand as, for example, leaning on the arm with the palm of the hand resting on a table, causes pain. 5. Pressing together the index finger and the thumb as in holding a pen causes pain if done one or two hours after playing a round of golf. She has been instructed by three well known professionals and her form is considered good. An improper grip or faulty swing can probably be ruled out as a cause of the trouble. What can the cause of this pain be and what can be done to relieve it permanently?
M.D., West Virginia.

ANSWER:—The history suggests an arthritis. Presumably x-ray films have been made and carefully studied, although this is not mentioned in the letter. If the trapezoid and second metatarsal joint are clear and show no changes, it would be well to scrutinize closely the x-ray film of the proximal row of carpal bones of the wrist, paying particular attention to the semilunar bone, which occasionally is the seat of a noninfectious aseptic osteitis called Kienböck's disease.

All foci of infection should be searched for and eliminated. If the condition is an arthritis, rest is essential, even to the extent of giving up golf for a season. A cock-up wrist splint may be worn, which will keep at rest the various component joints of the wrist and still permit movement of the fingers. If this fails to give relief, consultation with an orthopedic surgeon would be advisable.

THUMB SUCKING IN INFANTS

To the Editor:—What is the attitude of pediatricians toward thumb sucking in infants and children? Should one attempt to stop them or let the habit run its course? Is it thought that dentition and oral development are influenced by thumb sucking? W. E. Oldham, M.D., Lebanon, Ky.

ANSWER:—The opinion of pediatricians is somewhat divided with regard to the proper handling of thumb sucking. Some believe that the habit should be completely ignored in all infants under a year of age. Others favor the use of some restraining device, such as pasteboard splints on the arms, aluminum mitts or other coverings for the hands. The application to the thumb of bitter substances is of service only in the milder cases and even in such instances may not be of benefit.

Few pediatricians are willing to accept the view that thumb sucking may have a sexual basis. Curtailment of the thumb sucking may lead to the development of some substitute habit. Thumb sucking is more liable to occur when a child is about to go to sleep or when he is hungry.

Opinions seem equally divided as to the effects of thumb sucking. Some orthodontists are inclined to believe that the continued sucking will lead to malocclusion and deformity of the jaw; others do not concur but rather consider the etiology of malocclusion to be based on heredity and other factors.

If the habit is unduly frequent or of a combined type, that is, accompanied by hair pulling, nose rubbing and the like, it is probable that efforts should be made to overcome the habit. Mechanical restraint probably is the most effective method of treatment in such cases. In milder cases in which the habit is of infrequent occurrence, it may well be ignored.

SYPHILITIC MYELITIS

To the Editor:—A white woman aged 56 complained on March 5, 1940, of paresthesias of the feet, legs and lower part of the abdomen. There was a burning sensation in the right foot beginning at the plantar surface of the second toe and running back along the medial half of the plantar surface of the foot and up the leg. There was a feeling of tightness about the lower part of the abdomen and back. With the onset of these symptoms in January 1940 there was difficulty in walking. The sensory disturbances were distressing at night. She had lost 10 pounds (4.5 Kg.) since the onset of her illness. The patient is intelligent and there is no loss of memory. Speech is not affected. There are no headaches, vertigo, or gastrointestinal complaints. The appetite is good. Menstruation ceased at the age of 51. Her past medical history is negative. She has been married for thirty-one years, has never been pregnant, and states that her husband, aged 71, is in good health. The patient weighs 105 pounds (47.6 Kg.). There are no abnormalities of the skin, eyes, ears, nose, throat or lungs. The pulse rate is 84. The blood pressure is 176 systolic, 90 diastolic. Abdominal and pelvic examinations are negative. The gait is unbalanced, faltering and ataxic. Falling is apt to occur if a cane is not used. The pupils react normally to light and in accommodation. The patient's eyes were examined by an ophthalmologist and no abnormalities whatever were detected. There is no tremor. The tendon reflexes at the wrist and elbow are normal. The superficial abdominal reflexes are absent. The knee jerks are hyperactive. The Babinski reflex is questionable. The Romberg test is positive. The finger to nose test is well done. The heel to knee test cannot be evaluated because of spasticity of both lower extremities (adductor spasm?). Thermal and tactile sensibility is impaired in both lower extremities, the degree of impairment increasing from above downward. The urine is normal. On March 18 the red blood cells numbered 3,510,000, the hemoglobin 80 (Sohli), white blood cells 9,750, the differential normal. The blood Kahn reaction March 18 was positive. Spinal fluid examination March 29 revealed normal pressure, the Wassermann and Kahn reactions negative, white cells 4, globulins moderately increased, total protein 150 mg., colloidal gold curve 1122210000. My diagnosis was neurosyphilis, probably with early myelitis involving the lower dorsal and lumbar regions of the cord. Since March 30 she has received ten injections of bismuth subsalicylate in oil followed by ten 2 Gm. doses of trypanamide and is now on a second course of the bismuth compound. She is taking potassium iodide orally (60 minims, or 3.7 cc., of the saturated solution daily) and tolerates her treatment well. To date there has been no improvement in her nervous symptoms, although there is no evidence of progression. The positive neurologic signs remain the same. The weight remains the same. A red blood cell count repeated on July 11 showed 4,040,000 with a hemoglobin of 88 per cent. Blood tests repeated at another laboratory July 15 revealed the Wassermann negative, Kahn 4 plus and Kline 3 plus. I would appreciate your opinion as to the diagnosis. I understand syphilitic myelitis to be a diffuse meningeovascular lesion of the cord with general softening, amounting to infarction. The clinical and laboratory observations in this case seem to fit this diagnosis, except for the normal spinal fluid cell count, which would speak against meningeal involvement. What treatment would you advise? What is the prognosis? What of fever therapy in this case, and when should it be given with reference to drug treatment?
M.D., Ohio.

ANSWER:—From the description, the patient's condition may be classified as a myelopathy or a myelitis; or, in view of the serologic test, the possibility of a vascular type of neurosyphilis must also be considered. A report of the jugular compression test and a report of x-ray examination of the thoracic spine would be of help in making a diagnosis. The first blood count report raised the question of a pernicious anemia, so further study of blood smears and a gastric analysis with histamine may be helpful.

The results of treatment of patients who have a syphilitic myelitis are quite unsatisfactory. In view of the patient's age and type of involvement, the continued use of trypanamide and a bismuth compound would seem warranted. The use of fever therapy in this type of case is attended with considerable risk and small chance of improvement.

ARTHRITIS OR SERUM ARTHRALGIA

To the Editor:—A man aged 45 had no joint symptoms until he was given serum for pneumonia in February 1940. He developed a serum sickness and continues to have stiffness and pain in practically all his joints. The joints are not deformed but are tender. Warm baths and salicylates have been of no value. Can you suggest any treatment that might help? There are no evident foci and he is otherwise in good health.
M.D., Indiana.

ANSWER:—It is unlikely that articular symptoms of several months' duration are related to serum therapy. The articular symptoms of serum sickness generally last not more than a few days, in the experience of Boots and Swift, not more than nine days in any one joint. In serum sickness there occur, two or three weeks after the serum therapy, fever, urticaria, sometimes enlargement of lymph nodes and, in many cases, pain and tenderness of the joints, less often actual redness and swelling of joints. Arthralgia, rather than arthritis, is usually present. Analysis of the synovial fluid may reveal an increased cell count and the presence of the offending antigen.

In view of the persistence of the patient's pains, he apparently has some condition other than the arthralgia of serum sickness. He is approaching the age when degenerative (hypertrophic)

arthritis and its accompanying muscular stiffness are common. The latter generally can be readily differentiated from chronic atrophic (infectious) arthritis by making roentgenograms and estimating the sedimentation rate.

UNUSUAL SYMPTOMATOLOGY IN PERIARTERITIS NODOSA

To the Editor:—A woman aged 40, single, with a definite diagnosis of periarteritis nodosa, was given an ampule of metaphyllin 0.24 Gm. in a 10 cc. solution intravenously. Two and a half hours later she became disoriented and failed to respond to questions, repeating "vomit, vomit" and sucking on her fingers. There is a question of a temporary amaurosis. The left pupil reacted to light (the right dilated and fixed from a previous episode of retinal hemorrhage and blindness). Physical examination was otherwise negative. One hour later I was called because of a clonic convulsion with frothing at the mouth and coma. There was no bowel or bladder incontinence. The pulse was full and bounding. There were no sibilant or sonorous rales, which had been present for years on and off and which were noted early that morning. Nikethamide was given intramuscularly. Slow and irregular respirations soon appeared, to become deeper and more regular. One and a half hours later I returned because of another similar convulsion. The condition was as before. Nikethamide was given again. The patient remained comatose for another two hours. At that time she stirred and turned on her side. She looked up, recognized me and spoke to me. There were still moist rales in her chest. She was still disoriented. Four hours later she responded to questions and made plans for her family and for her own diet for the following day. She thought she "was dry" but didn't care for any food that night although she sipped a little water. She slept well through the night. The following morning her appetite was poor. She felt exhausted. She had vomited some orange juice. Sibilant rales were noted throughout both lungs. There was an equivocal Babinski sign on the left and a weak left ankle jerk. The abdominal reflexes were lively except for the lower left quadrant. She remembered nothing since a faintness coming over her the previous day at the beginning of the episode until seeing me some eight hours later. The blood pressure was now 132/80 (from 170/94 of the previous day). She has been taking epinephrine, iodides, ephedrine, bromides and metaphyllin (by vein) as necessity required for a number of years. For the last month there has been slight weekly vaginal bleeding, which this day was more profuse (this has occurred previously after metaphyllin). For a number of days there has been numbness of the toes relieved by heat and elevation, and which is now gone. Is it possible to tell me what occurred? No air, I am sure, was injected. I would not care to use the drug again if there is any relationship, but she feels that it has always helped her in the past.

M.D., Connecticut.

ANSWER:—It seems unlikely that the drug was responsible for the train of symptoms described in this case. Metaphyllin is theophylline with ethylenediamine. Less than 0.2 Gm. of theophyllin is contained in 0.24 Gm. of the compound. This dose is well within the limits of safety, especially if the injection is given rather slowly. From one and one half to two minutes should be consumed in injecting the drug. The fact that the patient had received many such injections previously would rule out sensitiveness to the drug. In addition to this, patients who are sensitive react promptly and not two and a half hours later.

In a disease with such protean manifestations as periarteritis nodosa it is much more likely that the symptoms described were the result of the disease itself, probably a cerebral thrombosis or the rupture of a cerebral aneurysm.

DEPILATORY PASTE

To the Editor:—Is there any contraindication to the use of a depilatory paste containing barium sulfide on the face, the paste containing 4 drachms (15 Gm.) of barium sulfide and 2 drachms (8 Gm.) each of powdered zinc oxide and powdered starch? Is it advisable to reduce the average exposure time of from one to two minutes if such a paste is used on the face?

M.D., Illinois.

ANSWER:—The depilatory paste mentioned is one of the formulas of Duhring and must be thinly applied to the area to be treated and allowed to remain until there is a slight sensation of burning (not longer than one or two minutes) and then scraped off. Such a paste when used repeatedly on the face is apt to cause dermatitis and conjunctival irritation, in addition to being unpleasant to the sense of smell because of its sulfide content. Since the process must be repeated with the reappearance of the hairs, there is great likelihood of irritation (dermatitis venenata) on the face, and it is well, therefore, to reduce the exposure time to a minimum. Other methods of depilation, e. g. electrolysis, in proper hands is a safer and more permanent procedure for removing superfluous hair if the involvement is not too extensive.

STERILIZING ADHESIVE TAPE

To the Editor:—I have the problem of sterilizing adhesive tape which may not be put to immediate use but which may have to be stored for several months. Can you tell me what method I can use without impairing the adhesive qualities of the tape? Will exposure to short wave diathermy kill bacteria unless there is sufficient heat developed to effect also the sticking power of the adhesive? If so, what wavelength would be most effective?

M.D., New York.

ANSWER:—Exposure to short waves is at best an uncertain method of sterilization of adhesive tape, and subsequent packing for storage would add to the technical difficulties involved. Sterilization with moist heat is the method of choice. One firm of manufacturers (Johnson and Johnson, New Brunswick, N. J.) produces a tape which, it is stated, may be so treated without impairment of its adhesive qualities. Sterilizable tape should be faced, it is said, with crinoline or some other cloth. It must be so placed in the autoclave that steam can freely reach the entire surface; i. e., it should lie in separated flat strips or sheets or in a loose roll. The manufacturers recommend 10 pounds pressure (240 F.) for thirty minutes. A minor problem is to prevent excessive drying during the period of storage, which would impair the adhesive quality.

FUNCTIONAL POSITION IN ANKYLOSIS OF THE HIPS

To the Editor:—What is the optimal functional position in bilateral ankylosis of the hips?

M.D., Pennsylvania.

ANSWER:—Abduction of from 10 to 15 degrees of each leg with slightest degree of external rotation probably would be considered best in the average case. This produces the broadest base of support for walking. There are some instances in which one must give consideration to the individual case; namely, some people would rather have the hips stiff in flexion so that they can sit, rather than in extension, which is better for standing, walking and lying. A court reporter may prefer the sitting position.

Another factor is the amount of movement possible in the lumbosacral area. Unfortunately so many victims of bilateral ankylosis have in addition ankylosis of the sacro-iliac and lumbosacral joints that they have no outlet in the lower back area to compensate in any measure whatever for the stiffness of their hips. Occupation and marital relations are important factors.

DYSMENORRHEA AND ARTIFICIAL MENOPAUSE

To the Editor:—A woman aged 36, married twelve years, with no children (she has never used contraceptives), has always had severe menstrual pain. In fact, no medication ever gave relief until about one year ago, when I started giving pantopon hypodermically. This seemed justified in view of the excruciating pain and of the fact that it is given only once a month. The effectiveness of pantopon is still as great as a year ago and she does not suffer nearly as much. Now this patient wants my opinion as to x-ray treatments for a therapeutic menopause. She argues that the chances of her having children are slight at this age after twelve years of sterility and that her life from now till the natural menopause would certainly be much happier without the dreaded periods. Would the symptoms of the menopause induced by irradiation differ at all from the symptoms of a natural menopause? Is the effect on sexual desire any different? I have studied this particular case for several years and have tried everything recommended for dysmenorrhea, including progesterone, chorionic gonadotropin and even a dilation and curettement, which was recommended by a gynecologist in consultation. All these were ineffectual. So I am anxious for an opinion on the effect of x-ray treatments.

M.D., New York.

ANSWER:—The symptoms of the menopause induced by roentgen or radium therapy are similar to and ordinarily not notably more severe than those of the natural menopause. There is persistence of satisfactory libido in nearly one half of the cases, although some decreased desire is to be anticipated.

In a case such as this, at the age of 36, most gynecologists would advise strongly against induction of an artificial menopause. An abdominal operation with removal of the menstruating portion of the uterus or resection of the presacral nerve would be the procedure of choice, provided palliative measures fail to bring comfort.

The following dysmenorrhea regimen merits a trial: Beginning three days before the expected onset of pain or menstruation, the patient should be outdoors as much as possible, be on a sparing diet, keep the bowels free and take 1 teaspoon of elixir of phenobarbital three times daily. With onset of pain or menstruation the patient should rest quietly, double the dosage of elixir of phenobarbital and take one-half grain (0.03 Gm.) of codeine sulfate every half hour until relief, not in excess of six tablets in twenty-four hours.

Medical Examinations and Licensure

COMING EXAMINATIONS

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in *THE JOURNAL*, December 21, page 2203.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, February 10-12. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral*. Part II, Cleveland, May 31-June 1. Final date for filing application is April 1. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. Parts 1-A and 1-B, Feb. 17. Final date for filing application is Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Part II, Groups A and B, Cleveland, May 28-June 1. Final date for filing application is March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. Cleveland, May or June. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF PATHOLOGY: *Oral and Written*. Cleveland, June 1-2. Final date for filing application is May 1. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: New York, March 30-31, following the Region I meeting of the American Academy of Pediatrics. Chicago, May 18, following the Region III meeting of the American Academy of Pediatrics. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF RADIOLOGY: *Oral*. Cleveland, May 30-June 1. Final date for filing application is April 15. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

Rhode Island July Report

Dr. Robert M. Lord, secretary, Division of Examiners, reports the oral and written examination for medical licensure held at Providence, July 11-12, 1940. The examination covered 8 subjects and included 75 questions. An average of 80 per cent was required to pass. Nine candidates were examined, all of whom passed. One physician was licensed to practice medicine by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1938)		83
Johns Hopkins University School of Medicine.....	(1920)		83
St. Louis University School of Medicine.....	(1939)		89.5
Hahnemann Medical College and Hospital of Philadelphia.....	(1939)	80, 85, 85, 88	
McGill University Faculty of Medicine.....	(1938)		86
Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin.....	(1937)		88.2
School	LICENSED BY ENDORSEMENT	Year Endorsement Grad.	of
Boston University School of Medicine.....	(1938)	N. B. M. Ex.	

California June Report

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports the written examination for medical licensure held at San Francisco, June 25-27, 1940. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. One hundred and sixty-three candidates were examined, 155 of whom passed and 8 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent

Book Notices

The Diagnosis and Treatment of Cardiovascular Disease. Edited by William D. Stroud, B.S., M.D., F.A.C.P., Professor of Cardiology, University of Pennsylvania Graduate School of Medicine, Philadelphia. Volumes I and II. Fabrikoid. Price, \$18, per set. Pp. 801; 1001-1825, with illustrations. Philadelphia: F. A. Davis Company, 1940.

This is a monumental contribution to the field of diseases of the heart and blood vessels. It covers the modern point of view fully. This is important, since the subject has undergone considerable change in the past two decades as regards (1) the aspects of cardiovascular fields emphasized, (2) the substitution of the functional for the purely morphologic point of view. These changes are clearly reflected in this treatise. The sixty-two chapters of this two volume textbook are contributed by fifty-six eminent American authorities, the majority of whom have themselves advanced the knowledge of the subdivision about which they write. Being, almost without exception, clinicians as well as investigators, they write from the practical side based on experience in handling patients. They have thus presented the practical information for diagnosis and therapy in addition to the general concepts of diseases of the heart and blood vessels. The influence of the American Heart Association, in which many of the authors have taken a leading part, is evident throughout the book, and it is crystallized in the chapter on the public health aspects of heart disease contributed by Marvin.

An idea of the scope of the volume can best be appraised by an enumeration of the various contributions (space does not permit much more in this review).

The introduction, written by Sprague and P. D. White, orients the reader with regard to the prevailing emphasis of the various aspects of the subject. Maude Abbott presents a brilliant summary of congenital anomalies. Rheumatic heart disease is covered in three chapters contributed by McEwen, Paul and Duckett Jones. Bacterial endocarditis is reviewed by William Dock; cardiovascular syphilis is covered in two chapters by Paullin and Minnick and by Stokes and Anderson. L. A. Conner reviews the subject of cardiac neuroses, Porter the effects of anemia and Durant that of pulmonary diseases. The interrelation of the kidneys and the cardiovascular system is beautifully

handled by Hayman. Barr has summarized the relationship of diseases of the endocrine system and the circulation, and Thomas the relationship of hyperthyroid activity and the heart. Soma Weiss presents an excellent review of the effects of nutritional deficiency diseases on the heart. Barber contributes the chapter on trauma, Porter and P. D. White the chapters on pericarditis, Roesler the one on cardiac enlargement, Vander Veer the one on chronic valvular heart disease and Fred Smith, Robert Lévy and Stroud the three chapters on coronary artery disease and angina pectoris. Bellet summarizes the subject of the blood supply of the heart, King the normal heart, Wolferth and Margolies the subject of heart sounds, Wilson, and Bellet and McMillan the field of electrocardiography, Margolies the field of roentgenography, Herrmann the subject of cardiac arrhythmia, and Bromer and Stroud the conditions of congestive heart failure and left heart failure (and paroxysmal cardiac dyspnea).

The general management of the cardiac patient is dealt with separately by several contributions: on digitalis by Stroud and Vander Veer, and by McMillan and Bellet, on quinidine by Kerr, on physical and spa therapy by Comstock and Stroud, and on rehabilitation in industry by Stroud. Surgery and pregnancy in the cardiac patient are amply discussed by Levine. The surgical treatment of heart disorders is reviewed by Beck, with special chapters on alcohol nerve block in angina pectoris by Grant and on total thyroidectomy by Blumgart and Riseman.

The subject of peripheral vascular diseases is begun by a consideration of normal blood pressure by E. V. Allen, of capillary circulation by DeGraff and Kossman, and of venous pressure by Schleiter. Shock is presented by Freeman, hypertension by Stieglitz and by Houston, low arterial pressure by J. H. Barach, arteriosclerosis by Eli Moschowitz, periarteritis nodosa by Farley, thrombo-angiitis obliterans by Buerger, erythromelalgia, lymphedema and sudden vascular occlusion by E. V. Allen, thrombophlebitis by N. W. Barker, aneurysm and auriculoventricular fistula by Hines, arteriosclerosis obliterans, acrocyanosis and Raynaud's syndrome by I. S. Wright, and vascular anomalies and varicose veins by de Takats. An excellent article on edema by Landis concludes the book.

From the foregoing outline it is obvious that some reduplication is unavoidable, but the extent of reduplication present in this book could have been considerably curtailed by judicious editorial deletions, and this would have improved the treatise and considerably abbreviated it. The fault inherent in any volume contributed by many authors is that the style is variable, and this is true in the present work. It is, however, unavoidable. There is the advantage of range of appeal, which satisfies various readers. Readers ranging from the medical student to the specialist in cardiovascular diseases will find much in this book which will interest them. The profuse use of illustrations, case reports, selected bibliographies and an excellent index enhance the value of the book. It is regrettable that in the final proofing the fact was overlooked that a few of the illustrations were upside down and that singular instead of plural reference to their own opinion was used in one of the chapters by the joint authors. By virtue of the division of topics discussed, some topics, for example myxedema heart, have been omitted. Considerable improvement might also have been attained in the book by a better arrangement of the sequence of the chapters and by subdividing it into major sections. The innovation of showing engravings and short biographies of the men who have made the milestones in cardiovascular diseases is appealing, especially since the engravings themselves are so excellently executed.

This treatise is a splendid cooperative effort and it should be in the library of every one who is interested in the subject of cardiovascular diseases. The reviewer can recommend the book no better than Sir Thomas Lewis, who in the foreword states: "The brilliant list of American authors of the present contents includes a score of names known in every part of the world where cardiovascular diseases have been intensively studied; they are known for the solid contribution of those who bear them to their subject. Rarely before has such a number of authoritative writers combined to place its views of a branch of medicine on record, and never before of cardiovascular disease; it is a guaranty to the reader that he is in direct or close contact with all the fountains of modern knowledge, the most important guaranty perhaps that any reader can be given."

Der Klinische Blick. Von Prof. Dr. Erwin Risak. Third edition. Paper. Price, 6.60 marks. Pp. 230. Vienna: Julius Springer, 1940.

Dr. Risak presents no new or startling discoveries. He merely presents a careful survey of objective clinical phenomena that are readily observable when the physician makes use of his five senses. He leads the reader on to the interpretation and coordination of these observations, proceeds to the development of what should be the birthright of every true clinician, namely insight or what is at times called clinical intuition, the ability rapidly to evaluate the importance of seemingly widely different phenomena, and to fit them into the harmonious picture of clinical syndrome or disease entity. A pupil of the school of von Hochenegg and Chvostek, and remotely of Bamberger, Skoda and Auenbrugger, Dr. Risak comes to this approach quite naturally and his contribution is useful. Particularly in this day when medicine in Europe must be practiced in mass, the capable clinician must have the ability to sort his material rapidly but surely. It is here that clinical insight, the "clinical eye," is of utmost value. Risak would by no means have the accessory laboratory aids or the use of the modern diagnostic armamentarium neglected, but he is quite right in stressing the significance of the art of medicine as an important though often neglected phase in our modern medical training. The book is well ordered. The first part concerns the physician, the second part the environment of the patient, and the third part, of approximately 150 pages, the phenomena to be observed in the patient. The presentation is both thorough and instructive but sufficiently informal and personal to be entertaining as well. Shrewd clinical observations illustrate and enliven the significant points, all of which have been selected from a practical point of view. It is to be regretted that nothing quite comparable to this little volume has appeared in the more recent American literature.

A Pioneer Doctor in Old Japan: The Story of John C. Berry, M.D. By Katherine Fiske Berry. Cloth. Price, \$2.50. Pp. 247, with 21 illustrations. New York, London & Edinburgh: Fleming H. Revell Company, 1940.

Dr. John Cutting Berry went to Japan in 1872 when he was 25 years old. He was the type of medical missionary who has done probably more for good will between Eastern and Western civilization than has any other pursuit. The Japanese published in their own language a short biography of his life, the first ever written about an American by the Japanese. Dr. Berry was decorated by the Japanese emperor and was hailed by the Japanese as the father of prison reform and social service work in their country. At the time of the celebration of the golden wedding of Dr. Berry the Japanese presented him with a marvelous Japanese vase; there were messages from innumerable Japanese leaders.

In the course of his medical education Dr. Berry studied under W. W. Keen and S. Weir Mitchell. He took also some lectures under Oliver Wendell Holmes. The writer has a fine sense of humor and intersperses her story with innumerable anecdotes. There are excellent pictures of Japanese civilization.

After leaving Japan in 1894 Dr. Berry settled in Worcester, Mass., as a specialist in diseases of the eye, ear, nose and throat. He practiced medicine until his eighty-eighth year. In 1918 he was appointed head of an American board to survey conditions in Japan. Thus he lived a long and useful life which was well worthy of the sympathetic record now available in this book.

Mucous Colitis: A Psychological Medical Study of Sixty Cases. By Benjamin V. White, M.D., Stanley Cobb, M.D., and Chester M. Jones, M.D. Psychosomatic Medicine Monograph I. Published with the Sponsorship of the Committee on Problems of Neurotic Behavior, Division of Anthropology and Psychology. Paper. Price, \$2. Pp. 103, with 30 illustrations. Washington, D. C.: National Research Council, 1939.

For years many gastro-enterologists have felt that the term "mucous colitis" is undesirable because in this disease the colon itself is normal and the distress is due only to nervous stimuli arising in a tired or psychopathic brain. Under the circumstances it seems unfortunate that the writers of this valuable little monograph decided to retain the term "colitis." Since the genitive ending *itis*, which meant originally "disease of a part," has come to mean in both the popular and the medical mind "inflammation," it seems wrong to use it in describing a disease in which the organ involved is not inflamed or ulcerated. The use of the term is particularly unfortunate when there is such a disease as true ulcerative colitis and patients are constantly

being confused. They get the idea that they have a serious and fatal disease and naturally become frightened. The remarkable contribution of White, Cobb and Jones is the demonstration now that, by injecting into healthy students a drug of the acetylcholine type which produces reactions similar to those of stimulation of the parasympathetic nerves, one can produce changes in the mucosa of the bowel which somewhat resemble those seen during an attack of mucous colic. Every gastro-enterologist will want to have a copy of this monograph within reach of his desk.

Berkeley Moynihan, Surgeon. By Donald Bateman. With a preface by Lord Moynihan. Cloth. Price, \$4. Pp. 354, with 8 illustrations. New York: Macmillan Company, 1940.

Unquestionably during his career Berkeley Moynihan was the most famed of all British surgeons. He was a frequent visitor to the United States and was the personal friend of many a great American surgeon. His biography has now been made available by Dr. Donald Bateman, who traces the life of the famous surgeon, describing his birth and his parenthood. Berkeley Moynihan derived many of his characteristics from a remarkable father and mother. Then came the decision as to whether or not the boy at the age of 15 would be developed for a military career or a career in medicine. He made his own choice and entered medical school in 1883. He had a retentive memory and great strength. He had planned after he entered medicine to join the army medical service but he came to the attention of the surgeon McGill and became a dresser. After graduation he was, however, appointed to become house surgeon for Mayo-Robson. Then comes an intimate account of the life of Moynihan as a young doctor and of his marriage. In 1914 the outbreak of the great war interrupted his work but gave him opportunity for fame. His first visit to the United States was in 1903, at which time he spoke at the College of Physicians of Philadelphia, discussing a paper by Dr. William J. Mayo on "Surgery of the Stomach and Duodenum." Following his return from America he introduced the use of rubber gloves and of the white coat into his surgery. It is interesting to read that because of this he was the subject of much ridicule. In the course of his development he practiced constantly the tying of knots and developed his manual skill. At the age of 40 he found himself being occasionally invited to speak in public and he soon developed a gift for witty and felicitous oratory. This accomplishment also played a great part in his advancement both in science and in public life. In July 1917 he again visited the United States in connection with our preparation for entrance into the World War. This volume makes available some of the best paragraphs from the many addresses which he made at that time in America and also provides some of his letters to his wife which discuss those travels. These are among the most interesting and valuable contributions in the book. The volume continues to trace the career of the great surgeon to the time of his death and affords many interesting sidelights on his career. It is readable and inspiring, picturing the great surgeon more as a man than as a scientist. It may well be added to the number of inspiring biographies now available in the field of medicine. If there is any criticism of the work, it is the absence of an index.

Sex in Development: A Study of the Growth and Development of the Emotional and Sexual Aspects of Personality Together with Physiological, Anatomical, and Medical Information on a Group of 153 Normal Women and 142 Female Psychiatric Patients. By Carney Landis et al. With a foreword by Nolan D. C. Lewis. Cloth. Price, \$3.75. Pp. 329. New York & London: Paul B. Hoeber, Inc., 1940.

Here is the report of a research carried out under the auspices of a special committee of the National Research Council. Some 295 women were interviewed as to their sex life. They had physical and gynecologic examinations, and a number of experts in the field of sex study took part in an analysis of the results. It was, of course, impossible to submit each one of these women to a psychoanalysis. The method was instead the study and tabulation of material from medical and psychiatric case histories and reports. Each person interviewed was presented with a series of cards. Each card contained a single question. The answers were recorded verbatim. Next came an interview with questions concerning the facts and fantasies related to psychosexual development. The interview was supplemented by two questionnaires, one dealing with vocational interest and the other

with a marriage inventory. Then came physical examination, roentgenologic studies of the pelvis and a psychiatric case history. The work is divided into chapters dealing with adolescence, adult sex practices, marriage adjustments, course of development, psychiatric studies of normal women, homo-erotic women, unhappily married women and psychopathologic personalities.

The evidence developed indicates that psychosexuality has its origins long before puberty. The way in which sex knowledge is gained seems to affect later attitudes. The child who has many illnesses or who is continually sick frequently exhibits difficulties in personal adjustment in adult life. The most important problem which a girl faces in adolescence is that of freeing herself from family ties. The onset of menstruation does not seem to have any radical effects in personality formation. Masturbation is a common practice which usually disappears without untoward effects on the personality. One woman in every four interviewed had sexual intercourse before marriage, with a higher percentage among girls with native born parents than among girls with foreign born parents. Apparently the determination of sexual intercourse before marriage depends in part on the standards of the social group to which she belongs, her psychology and her physical attractiveness. The evidence showed that one wife out of every three is sexually maladjusted. These and many other facts became apparent from the psychologic aspects of this study. From a physical point of view there were surprisingly few anatomic or physiologic differences between normal woman and those who suffered from functional or mental disturbances. Tendencies toward the male body form were found associated with homo-eroticism. The chief finding was the observation that the neurotic personality represents a style of life which is consistent from an early age. The volume is supplemented with samples of the examination forms that were used, tabular data, an extensive bibliography and a good index.

The International Medical Annual: A Year Book of Treatment and Practitioner's Index. Edited by H. Letheby Tidy, M.A., M.D., F.R.C.P., and A. Rendle Short, M.D., B.S., B.Sc. Fifty-Eighth Year, 1940. Cloth. Price, \$6. Pp. 545, with 127 illustrations. Baltimore: William Wood & Company, 1940.

This work is now in its fifty-eighth year. It is a compilation of contributions by a considerable number of British physicians who, through a system of abstracts of recent medical literature, keep knowledge up to date. The book is compiled on an alphabetical basis. It is freely illustrated and has an adequate index for ready reference. As a compilation of the literature of the previous year, with particular reference to the British point of view, it may be unhesitatingly recommended.

Tratado de enfermedades nerviosas. Por Luis Barraquer Ferré, Ignacio de Gispert Cruz y Emilio Castañer Vendrell, jefe y auxiliares respectivamente del Departamento de neurología del Hospital de la Santa Cruz y San Pablo de Barcelona. Tomos I y II. Cloth. Pp. 1,154, with 448 illustrations; 1,108, with 396 illustrations. Barcelona & Buenos Aires: Salvat Editores, S. A., 1936, 1940.

These two large volumes are said to be based mainly on the clinic and teachings of Dr. L. Barraquer Roviralta of the Hospital de la Santa Cruz y San Pablo de Barcelona, to whom it is dedicated. The preface by Pierre Marie is worthy of Mark Twain. After a brief historical sketch which is hardly more than a list of names the authors begin with a discussion of the methods of examination, which is adequate although physiologic observations are interspersed in a manner more confusing than illuminating. This section covers 270 pages.

The treatise proper begins with a section on the peripheral somatic nerves, which is good; the discussions are brief and generally accurate and there is an excellent description of the polyneuritis of leprosy. Nothing is said of the possibility that avitaminosis may play a role in the causation of alcoholic polyneuritis. The authors state that paralysis of the glossopharyngeal nerve causes dysphagia, a statement not confirmed by the results of surgical section of that nerve. Experience gained in the Spanish war is clearly reflected in the discussion on wounds of the nerves of the extremities. The brief remarks concerning tumors of the peripheral nerves are inadequate. Proper advice is given concerning the surgical treatment of various neuralgias.

The second and much longer section of the treatise concerning diseases of the spinal cord begins with a brief and unrelated sketch of the histology and histopathology of the central nervous

system. Then follows a short discussion of the anatomy and physiology of the spinal cord, after which the various diseases follow in encyclopedic fashion, each one being discussed in all its phases, including pathology. One notes an unusual chapter on echinococcus in the spinal canal. The second volume begins with 197 pages on the sympathetic nervous system in which American work is quoted at second hand if at all. Then follows a chapter on disorders of the extrapyramidal system, as though they had nothing to do with the brain.

The third section of the treatise deals with the diseases of the brain; extrapyramidal diseases such as Parkinson's disease and Wilson's disease were dealt with before. The discussions of cerebral diseases follow the same lines as do those of the spinal cord; after an anatomic introduction and short chapters on aphasia and apraxia the various diseases are taken up one by one and discussed from every point of view. The discussion of brain tumors occupies 140 pages and again one has the impression that American work is quoted at second hand (no bibliography is appended to this treatise).

The work is well illustrated with many interesting original photographs. One gains the impression that the authors are thoroughly familiar only with French neurology. Recent medical advances, such as quinine for myotonia congenita or potassium for periodic family paralysis, are not mentioned. The work is a compilation, doubtless useful in Spain; but the North American neurologist, with Wilson's masterpiece at his disposal, will rarely find need to consult it.

The Art of Useful Writing. By Walter B. Pitkin, Professor in Journalism, Columbia University, New York. Cloth. Price, \$2. Pp., 261, with illustrations. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1940.

Professor Pitkin has been author, dean and teacher and has previously written books on the art of rapid reading and on the art of learning. He recommends that the way to learn to write usefully is first to learn to write much. He recommends particularly study of condensation. In his own practice he learned eventually to write 1,500 words an hour and he now claims that he can write 10,000 words in finished book copy in nine consecutive hours. He recommends also that every writer plan to organize his information in useful files. His book is full of useful information but whether or not it is possible by the use of a book of this kind to become a writer one can only say that Mr. Pitkin says that it is. He provides innumerable exercises and plans for study. No doubt any one who has a talent and an urge for writing will be helped by this book. As an old practitioner in the writing field, the reviewer is inclined to believe that without this urge and talent any amount of sweat and exercise will not produce writing that is useful or salable.

Die Entzündungsbestrahlung. Von Dr. med. habil. R. Glauner, Dozent für Röntgenologie an der Universität Köln. Boards. Price, 15 marks. Pp. 190, with 14 illustrations. Leipzig: Georg Thieme, 1940.

Illustrative of the enlarging field for application of roentgen therapy other than in the treatment of cancer, this book is a welcome addition to the literature, constituting an excellent summary of the known technical and clinical facts relative to the subject. After a brief historical introduction and a discussion of the concept of inflammation, the author proceeds to the full consideration of the effect of the roentgen rays on local inflammatory processes from the standpoint of the physical and chemical changes, the blood vessels, the exudates, the mesenchyma and ferments. Next comes the discussion of the influence of the roentgen rays on the exciting causes of inflammation and on the general defensive mechanism of the organism against inflammation, including the antibactericidal blood and serum reactions, the reticulo-endothelial systems, the action of the protein bodies, the blood picture and the vegetative nervous system. The clinical subsidence of experimental inflammation under roentgen irradiation is next studied from the standpoint of bacterial, mechanical and chemical inflammation. Then the author proceeds to a general clinical consideration of anti-inflammatory irradiation, giving the indications and contraindications, general technic and dosage. The second part of the book is devoted to a discussion of radiation therapy in inflammations by systems, including a long list of inflammatory lesions in which the value of roentgen therapy is but slightly appreciated by the majority of the medical profession. This book, which is

gotten up in such an authoritative manner, should serve to stimulate a much wider use of roentgen therapy in the treatment of inflammations.

Three Famous Occultists. Dr. John Dee. By G. M. Hort. Franz Anton Mesmer. By R. B. Ince. Thomas Lake Harris. By W. P. Swainson. Cloth. Price, \$2. Pp. 190. Philadelphia: David McKay Company, [n. d.].

In the sixteenth century John Dee practiced as an astrologer. In those days the drawing of horoscopes was considered a science. Dee actually drew horoscopes for Queen Mary and for her sister Princess Elizabeth. Among other contributions he wrote a work on naval defense. Early in his career he became interested in psychic manifestations, recording his dreams and other phenomena. He also is credited with having practiced crystal gazing and the original crystal is still available in the British Museum.

Franz Anton Mesmer has been the subject of many biographies. He was the originator of magnetic healing, constantly in debate with the medical faculty of his time. In 1784 a commission was appointed to investigate the claims of animal magnetism and published a report which refuted his claims. At that time the scientific study of suggestion was not yet known. A description of his technic indicates that the results were secured by the power of suggestion, which was enhanced by the laying on of hands and by some complicated apparatus.

The third of the occultists, Thomas Lake Harris, was an Englishman who came early to America. In 1844 he was a Universalist preacher in New York. He became an occultist in 1850, when he first experienced what he termed "internal respiration." As was customary in those days, he formed a community to be called the Brotherhood of the New Life, which practiced occultism in a form which was apparently a mixture of astrology, alchemy and other esoteric manifestations. He had a system of religious philosophy based on christianity, and he claimed to have overcome death. When he himself died, many of his followers lost interest.

Government and Economic Life: Development and Current Issues of American Public Policy. Volume II. By Leverett S. Lyon and Victor Abramson. With the collaboration of Charles L. Dearing, et al. The Institute of Economics of The Brookings Institution Publication No. 83. Cloth. Price, \$3.50. Pp. 1,301. Washington, D. C.: Brookings Institution, 1940.

This is the second volume of a series on American public policy in relationship to economic life prepared through the Brookings Institution and published by it. In this volume the major portion of the discussion concerns government and the special treatment of private enterprise. One chapter deals with the activities of the government in the field of foods and drugs. There are also chapters on public relief and on social security. In their concluding observations the authors incline to the view that "our economy has reached a stage which is denominated as 'mature' and that as a result there is no longer any hope that we shall be able to come near the full employment of our productive resources without a continuous program of extensive public spending designed specifically to promote the utilization of idle men and plant." They recognize that it has not been demonstrated by economic analysis or by practice that the means now in operation for meeting the problem of unemployment will do more to meet the situation than the less elaborate programs of the early thirties. They say, however, that a permanent program of extensive governmental spending raised great questions of effectiveness and perhaps the survival of private enterprise.

A Surgeon Explains to the Layman. By M. Benmosché, M.D. Cloth. Price, \$3. Pp. 317, with diagrams by Bhola D. Panth. New York: Simon & Schuster, 1940.

While there are innumerable works of medicine planned primarily for the public, no one has previously attempted to inform the lay reader concerning all the technical details and background of surgical procedures. To this extent Dr. Benmosché is a pioneer. The information is for the most part sound and readable. He does not attempt to cover the history of surgery as in Graham's excellent book "The Story of Surgery." If any one wants to know about his operation before he has it, there is probably no better guide. However, from the point of view of the patient there may be some question as to the desira-

bility of a work of this character. In every instance the reader is made to feel that the decision of when to operate or whether or not to operate at all is an exceedingly difficult one. Incidentally it is a task which the surgeons find sufficiently difficult without having to enter into debate with the uninformed patient. Of chief value in the work are the simple discussions of the anatomy of various portions of the body. Particularly impressive are the final discussions of surgery of the chest, the brain and the heart. Quite recently the picture periodicals have illustrated every step of several surgical operations and there has been at least one broadcast directly from an operating room. Thus a beginning has been made. It will be interesting to observe the ultimate effect of information for the public concerning the technical details of operative procedures.

Electric Light for the Farmstead. Prepared by Bureau of Agricultural Chemistry and Engineering and Home Economics. U. S. Department of Agriculture, Farmers' Bulletin No. 1838. Paper. Price, 10 cents. Pp. 61, with 43 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1940.

This bulletin stresses the importance of good lighting and discusses in detail the essentials for good lighting. Further, it describes methods for providing good light for the farmhouse. The types of electric outlets, remodeling old lighting installations and equipment as well as lighting the farm yard and lighting the farm buildings are discussed. Information on planning lighting for farm buildings is given and is based on observations and records of the Department of Agriculture.

Pharmacology and Therapeutics. By Arthur R. Cushny, M.A., M.D., LL.D. Twelfth edition revised by C. W. Edmunds, A.B., M.D., Professor of Materia Medica and Therapeutics in the University of Michigan, Ann Arbor, and J. A. Gunn, M.A., M.D., D.Sc., Professor of Pharmacology and Director of the Nuffield Institute for Medical Research, University of Oxford, Oxford. Cloth. Price, \$6.50. Pp. 852, with 66 illustrations. Philadelphia: Lea & Febiger, 1940.

Since its first appearance in 1899 this work has been enjoying increasing popularity in Great Britain and the United States as a standard textbook and as a reference book on the subject of pharmacology by teachers, students and practitioners. Considerable revision has been made in the twelfth edition, beginning with the title, which was formerly "A Text-Book of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease" but now bears the simplified wording "Pharmacology and Therapeutics," extending through the introduction, the subject material and the index. Some of the changes are minor in nature but many involve considerable revision and even the addition of subjects formerly foreign to this book. Hardly a section has escaped some revision, but included in the sections which have undergone major changes, rewriting or additions are those describing the heavy metals and metalloids, alcohol-chloroform group, soporifics or hypnotics, local anesthetics, nicotine group, drugs of internal secretion and the vitamins. Several totally new descriptions have been inserted, including pharmacologic syndromes in the introduction, benzedrine, sex hormones, sulfanilamide, sulfapyridine and allied compounds and mandelic acid. These additions account for most of the increase in size of forty-four pages.

The section on the opium series remains as excellent as ever and includes a new member, bulbocapnine, an alkaloid closely related to apomorphine. One of the most useful and unique features in Cushny's Pharmacology and Therapeutics has been the classification of drugs according to their therapeutic uses. The student has always appreciated this section.

It is difficult to prepare a textbook on pharmacology for two countries such as Great Britain and the United States of America, as there is considerable difference in the nomenclature. For example, butyl-bromallyl barbituric acid is known as pernoc-ton in England and this is the name which appears in the text. In the United States the preparation is known as pernoston. Another example is seen under the section on avertin. In the British market avertin is supplied as avertin fluid but on the American market it is supplied as avertin with amylene hydrate, the amylene hydrate possessing anesthetic properties almost equal to those of avertin. However, even with such differences the subject material is so clearly and interestingly written that even the student will encounter few difficulties in his reading.

Although the index has been enlarged, it still appears to be too conservative for a book which contains so much information.

Unfortunately, the publishers have changed the color of the cover from the former familiar green to a red which is not unlike the covers of other well known books on pharmacology. No longer can one go to the library and easily pick out this book by its distinctive color. However, it will still remain one of the most popular works on pharmacology.

A Manual of the Common Contagious Diseases. By Phillip Moen Stimson, A.B., M.D., Assistant Professor of Clinical Pediatrics, Cornell University Medical College, New York. Third edition. Fabrikoid. Price, \$4. Pp. 465, with 60 illustrations. Philadelphia: Lea & Febiger, 1940.

Complete revision of a previously excellent textbook on the contagious diseases has produced here a book of great value. The subjects discussed include the principles of contagion, serum reactions, detailed description of the common contagious diseases, general management of these disorders, and management in boarding schools and homes. The material is presented briefly and the appended references increase the value of the work. Included is a discussion of the use of sulfanilamide and sulfapyridine. The book covers practically every phase of the subject without wordiness, so that physicians, students and nurses will find satisfaction in having this volume at their disposal.

Behind the Surgeon's Mask. By James Harpole, pseud. Cloth. Price, \$2.75. Pp. 308. New York: Frederick A. Stokes Company, 1940.

Here is another collection of interesting anecdotes from the practice of medicine by a British writer who has exceptional qualities in the field of letters. He has, moreover, an excellent sense of the dramatic and is able to make fascinating the incidents which many another physician might pass as commonplace. Both doctors and layman will find this book interesting. Moreover, it has none of the aspects of horror or tribulation which make many such works forbidden for the invalid.

A Survey of the Hospital Dietitian and Her Job. Parts I and II. By S. Margaret Gillam, Department of Nutrition, The New York Hospital, New York. Reprinted from Journal of the American Dietetic Association Vol. XVI: Nos. 6 and 7, 1940. Paper. Pp. 41. Chicago, 1940.

This is a report of a study of the hospital dietitian and her functions, activities and professional relationships. It is based principally on the questionnaire method.

Aids to Inorganic Chemistry. By R. G. Austin, B.Sc., A.I.C., F.R.M.S., Associate of University College, Southampton. Cloth. Price, \$1.50. Pp. 348. Baltimore: William Wood & Company, 1940.

This brief handbook provides the fundamental information regarding inorganic chemical substances that is necessary to all students in elementary courses on chemistry. The book should be especially valuable as an aid in preparation for examination.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Foot Drop Following Operation on the Knee; Res Ipsa Loquitur.—The plaintiff ruptured the exterior lateral and posterior crucial ligaments of his left knee and engaged the defendants to repair the damage. An operation was performed consisting of the removal of the damaged portions of the ligaments and the substitution of new material obtained from the fascia lata and biceps femoris muscle of the left leg. After the operation, the plaintiff began to suffer from a foot drop, and an examination by physicians other than the defendants disclosed that the peroneal nerve, the nerve supply to the muscles which raise the foot, was severed in the vicinity of the knee. The plaintiff then sued the defendants, alleging negligence, and judgments for the defendants resulted. After the case had been considered by the district court of appeal, California (80 P. (2d) 96; abstr. *J. A. M. A.* 112:1419 [April 8] 1939), the plaintiff appealed to the Supreme Court of California.

The medical testimony in this case, said the Supreme Court, showed without contradiction that, although the severance of the peroneal nerve is something which ordinarily does not occur in operations such as that performed in this case, yet even

when the precautions prescribed by the approved technic are taken, there may be a break of or an injury to the nerve in from 5 to 9 per cent of the cases. The court could find nothing startling about such evidence and was of the opinion that it afforded no basis for the recovery of damages. Probably in any operation, the court observed, there is some hazard which the medical profession recognizes and guards against but which is not always overcome. To say that the doctrine of *res ipsa loquitur* permits the recovery of damages in every case where an injury does not ordinarily occur would place a burden on the medical profession which the law has not heretofore laid on it. On the contrary, the law has never held a physician or surgeon liable for every untoward result which may occur in medical practice. It requires only that the physician shall have the degree of learning and skill ordinarily possessed by physicians of good standing practicing in the same locality and that he shall use ordinary care and diligence in applying that learning and skill to the treatment of his patients. Whether he has done so in a particular case is a question for experts and can be established only by their testimony. When the matter in issue is one within the knowledge of experts only and is not within the common knowledge of laymen, the expert evidence is conclusive. Negligence on the part of a physician will not be presumed; it must be affirmatively proved. In the absence of expert testimony it will be presumed that a physician exercised the ordinary care and skill required of him in treating his patient.

It is true, the court continued, that in a restricted class of cases the courts have applied the doctrine of *res ipsa loquitur* in malpractice cases. But it has been invoked only where a layman is able to say as a matter of common knowledge and observation that the consequences of professional treatment were not such as ordinarily would have followed if due care had been exercised. For example, it has been applied in California where a sponge was left in the body of the patient, where the patient was burned by the application of hot compresses or heating apparatus or through the operation of an x-ray machine and where the patient sustained an infection through the use of an unsterilized hypodermic needle. In each of these situations, however, the rule was applied because, in the opinion of the court, common knowledge and experience teaches that the result was one which would not have occurred if due care had been exercised. In the present case, however, an entirely different situation existed. Here what was done lies outside the realm of a layman's experience. Medical evidence is required to show not only what occurred but how and why it occurred. That evidence in the present case established beyond question, the court thought, not only that the peroneal nerve may be injured even when due care is used but that this unfortunate result invariably occurs in a limited number of cases. The doctrine of *res ipsa loquitur* is therefore entirely inapplicable and no malpractice was proved. The court, therefore, affirmed the judgments for the defendants.—*Engelking v. Carlson (Calif.)*, 88 P. (2d) 695.

Optometry: Sale of Eyeglasses by Optometrist Subject to Retail Sales Tax.—In two decisions, one emanating from Pennsylvania and the other from California, the question of the applicability of a retail sales tax to sales of eyeglasses by optometrists was decided. In each case the optometrist, after testing his patient's eyes and prescribing glasses therefor, sent the prescription to a dispensing optician, received the glasses therefrom and then delivered them to the patient. The bill that the optometrist subsequently sent to the patient included a fee for his professional services and a profit from the sale of the eyeglasses.

In *Kamp v. Johnson*, the plaintiff, an optometrist, sued the treasurer of the state of California to recover the amount of a tax which the optometrist had paid under protest. He contended that he was not subject to the provisions of the California Retail Sales Tax Act of 1933 because he was engaged in the practice of a profession and the furnishing of eyeglasses was purely incidental to the rendering of professional services. From an adverse judgment the optometrist appealed to the Supreme Court of California. In affirming that judgment, the Supreme Court held that the fact that the plaintiff practiced a profession was

immaterial because all the elements determinative of liability under the Retail Sales Act were present, i. e., a retail sale of tangible personal property for use by the patient and not a sale for resale, a transfer of title to the patient and the payment of a consideration therefor. In the judgment of the court the tax properly fell on the optometrist, since "the tax must be paid at some time with respect to all tangible personal property sold for use or consumption."

In *Commonwealth v. Miller*, the state of Pennsylvania sued the defendant optometrist to collect a tax assessed under the Pennsylvania Mercantile License Tax Act of 1899. It was conceded that the defendant was not liable for payment of the tax with respect to any income derived from his professional services in examining and measuring the vision of the eyes, prescribing glasses and fitting them after they were made. The defendant contended, however, that he should be declared exempt from the tax as to the selling of eyeglasses because an optometrist in selling glasses is in the same position as a dentist selling bridge-work or a physician supplying medicine to his patients. From an adverse judgment the optometrist appealed to the Supreme Court of Pennsylvania. The making and selling of bridgework by a dentist, said the Supreme Court, and the supplying of medicine to patients by a physician, instances in which the state "has very correctly not attempted to collect the mercantile tax," are radically different from the selling of eyeglasses by optometrists. In the case of the dentist, said the court, the preparation of bridgework necessitates considerable professional and scientific skill, labor and design on the part of the dentist. In the case of the physician, it is quite obvious that the furnishing of medicine to a patient is an inherent part of a physician's professional services in the treatment of sickness and disease. But the optometrist in selling eyeglasses is engaged in a business not at all necessary to his profession. He does not grind the lenses nor place them in their fittings. He plays no part in making or creating the eyeglasses. The glasses are handed to him by the maker, the optician, and he makes any necessary adjustment to fit them to the patient's head, but in so doing he makes no real change in the lenses or frames as such. No skill, scientific or otherwise, of the optometrist is required, since the scientific work has already been performed by the optician in making the glasses. In the judgment of the court the sale of eyeglasses, tangible chattel, is readily separable from the essential professional service of the optometrist, and such sale properly belongs to the occupation of the optician and is not necessary to the practice of optometry. The retail optician has always been subject to the mercantile tax and the optometrist cannot invade the optician's field of business, be a vendor of merchandise, and then claim immunity from the tax merely because he is also engaged in the profession of optometry. The court held, therefore, that the defendant was subject to the tax, and so it affirmed the judgment in favor of the state.—*Kamp v. Johnson (Calif.)*, 99 P. (2d) 274; *Commonwealth v. Miller (Penn.)*, 11 A. (2d) 141.

- Western Section, American Laryngological, Rhinological and Otolological Society, San Francisco, Feb. 1-2. Dr. Robert C. Martin, 384 Post St., San Francisco, Chairman.
- Society of Surgeons of New Jersey, Newark, Jan. 29. Dr. Walter B. Mount, 21 Plymouth St., Montclair, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Pulmonary Embolism and Heart Disease.—White summarizes his experience of twenty years with pulmonary embolism in association with heart disease by recounting the increasing frequency with which he has recognized the condition, the possible confusion in diagnosis, the frequency with which it complicates heart disease and the helpful signs of its presence. From 1920 to 1930 among 4,000 patients he made an initial definite diagnosis of pulmonary embolism simulating or complicating heart disease in only 9 cases and a questionable diagnosis in only 7. Among 3,350 patients in the last decade the definite diagnoses have increased from 9 to 66 and the questionable ones from 7 to 39. Of the 75 definite cases only 29 were diagnosed in the first sixteen of the twenty years, while 46 cases were encountered among 1,350 patients in the last four years. The author is certain that this increase in the last few years has not been actual but that a large part of it has been due to better recognition of the condition. Twenty-eight of the 75 definite cases simulated and 47 complicated heart disease. The cardiac diagnoses in which pulmonary embolism or infarction occurred as a complication were coronary disease, mostly with myocardial infarction and with or without hypertension, in 26; rheumatic heart disease, mostly with mitral stenosis and auricular fibrillation, in 15; hypertensive heart disease in 2, patent ductus arteriosus with subacute bacterial endocarditis in 1 and cardiac enlargement with no other evident abnormality than chronic auricular

fibrillation or flutter in 3. Peripheral phlebitis was evident in only a few cases, but it is probable that the majority might have shown such a lesion if the veins could have been explored; at least that is the lesson to be derived from the postmortem observations in which phlebitis that gives little or no clinical evidence of its presence is found in 70 per cent of cases of medical pulmonary embolism. Pulmonary embolism has failed to attract the interest and attention it has deserved from general practitioners as an important medical disease in nonsurgical and nonobstetric cases. Usually pulmonary embolism is either so mild or so rapidly fatal that characteristic electrocardiographic abnormalities are not present or the patients are examined only after the height of the effect of the pulmonary arterial obstruction has passed. Pulmonary embolism and infarction are easily overlooked, especially in the presence of congestive heart failure, when they are most common; or they are erroneously diagnosed as pneumonia, congestive heart failure or coronary thrombosis. Clues to the diagnosis lie in unexplained fever, leukocytosis, tachycardia, faintness, prostration, dyspnea or even jaundice, especially in a patient with heart disease.

Mechanism of Renal Hypertension.—Muñoz and his associates epitomize the present knowledge of the mechanism of renal hypertension as follows: Renal ischemia determines the secretion of "renin," which is an enzyme and acts on a blood globulin ("hypertensin precursor") and gives rise to a substance ("hypertensin") which produces vasoconstriction. Another enzyme, "hypertensinase," which destroys hypertensin, is present in blood and body tissues. A better understanding of the mechanism of renal hypertension may suggest the treatment of this disease which should aim at suppressing or diminishing the secretion of renin by the kidney, inhibiting the reaction of renin with blood globulin, diminishing the amount of hypertensin precursor and inhibiting the action of hypertensin by increasing the amount or the activity of hypertensinase or some other neutralizing agent. After injection of renin into chloralosed dogs, the hypertensin precursor decreases and even disappears from their blood. After nephrectomy, the hypertensin precursor increases and hypertensinase decreases.

Clinical Experience with Sulfamethylthiazole.—Brown and Herrell review their clinical experience with the use of sulfamethylthiazole in 30 cases of pneumonia, 7 of septicemia, 5 of acute bacterial endocarditis, 5 pelvic infections, 4 osseous infections, 25 cutaneous infections, 13 infections of the ear, nose and throat, 3 urinary infections and 14 cases of miscellaneous infections; a total of 106 cases. The drug was administered orally to the majority of the patients in doses similar to sulfanilamide and sulfapyridine. However, larger doses were frequently used for and tolerated by the severely ill patients. The sodium salt of sulfamethylthiazole was used intravenously for 3 patients and it significantly elevated the concentration of the drug in the blood. Sulfamethylthiazole orally produced concentrations of the free drug in the blood similar to but somewhat lower than those that result from sulfapyridine. A minimal amount of conjugation occurred with sulfamethylthiazole. The results obtained to date from its use seem to substantiate experimental predictions. *Staphylococcus aureus* and *Diplococcus pneumoniae* (type I) infections in particular seem to respond to treatment. With the exception of lower motor neuron involvement in 3 cases and of cutaneous eruptions in 9, toxic effects seemed to be less than those encountered following the use of sulfapyridine and sulfanilamide. Significant nausea and emesis occurred infrequently. The danger of lower motor neuron involvement makes it unwise to use sulfamethylthiazole for mild infections caused by *Staphylococcus aureus*. However, a fulminating infection which carries a high mortality rate far outweighs the danger of toxic manifestations from drug therapy, and this drug or a related preparation may be indicated.

Endemic Riboflavin Deficiency in Children.—During a period of two years Spies and his colleagues examined repeatedly 472 children, from 5 months to 14 years of age, of parents with deficiency diseases. They paid particular attention to their physical and mental development and to the presence or absence of lesions of riboflavin deficiency. They made a clinical diagnosis if one or more of the deficiency lesions ("chei-

losis," the reddened macerated areas at the angles of the mouth and the linear lesions or fissures of the lips and the ocular symptoms characterized by bulbar conjunctivitis, lacrimation, burning of the eyes and failing vision) were present. Cheilosis was observed in 113 cases, linear lesions in 93 and ocular manifestations in 167. These children were usually underweight and underdeveloped for their age. Many were apathetic and indifferent and made poor progress in school. Frequently they complained of sore mouths and burning and itching eyes. The symptoms waxed and waned with the seasons and with changes in the quality of the dietary, but they appeared most frequently during the spring and summer. Increased exercise and infections seemed to precipitate the appearance of lesions in borderline cases. The response of the children to synthetic riboflavin or substances rich in it was gratifying. The cheilosis healed rapidly, the ocular symptoms disappeared and their general health improved. Unless therapy was continued or the diet improved, the disease tended to recur. Dietary studies showed that almost without exception the mothers of these children had subsisted on grossly inadequate diets during pregnancy and lactation, and also that the majority of the infants and children studied received only 35 per cent of the estimated requirement of riboflavin. The average case responded satisfactorily to the oral administration of 1 mg. of riboflavin three times a day, 1 ounce of brewers' yeast or liver extract daily.

Tetanus Toxoid Immunization in the Navy.—Hall summarizes the work on active immunization against tetanus which began in 1934 on the fleet hospital of the United States Navy, the U. S. S. *Relief*. Since then 3,446 midshipmen of the Naval Academy as well as other navy personnel and dependents have been immunized. The freedom from reactions in the use of alum precipitated toxoid has been universally noted. Soreness of the arm, disappearing in forty-eight hours or sooner, occurred from injections given intramuscularly. When injections were made subcutaneously a cutaneous reaction occurred which was greater in intensity the closer to the skin the mate-

rial was placed. This was followed by a subcutaneous induration which remained as a nodule for one or two weeks. The intramuscular route was chosen because of its relative freedom from local reaction. It has been suggested that immunity is enhanced when the material is placed in the skin. This has not been the observation in the Navy, as no uniformly higher level of antitoxin titer was observed in those who had a violent cutaneous reaction than in those in whom the injection was made intramuscularly and who had little or no cutaneous reaction. General reaction has been minor, seldom amounting to more than mild malaise and an occasional minor and short rise in temperature. Some reactions were encountered when a certain toxoid was used. The reactions were probably caused by inadequate washing of the alum precipitated toxoid in the course of preparation. No case of tetanus among the immunized individuals has as yet been reported. The actual antitoxin level in the blood is not of prime importance. Basic immunity, or the ability of tissue to react with the production of antitoxin, is the essential condition. The plan adopted in the Navy is to give two injections eight weeks apart as basic immunization, injection at the time of injury, if deemed necessary to raise blood antitoxin rapidly, and injection every four years after basic immunization to maintain immunity at a high level. All midshipmen at the U. S. Naval Academy are now immunized with alum precipitated tetanus toxoid. Such immunization is ideally fitted to the needs of the military services and to other groups which can be well controlled. Its universal adoption in such groups seems inevitable.

Prevention of Pernicious Anemia.—Askey believes that the challenge for the future must be to diagnose pernicious anemia before blood and nervous system changes appear. He presents the accumulating evidence that potential cases are to be looked for in the relatives of patients and suggests a scheme by which they may be recognized in the latent stage. Pernicious anemia has been found in several members of families to an extent far above the expectation from chance alone. Increased frequency of pernicious anemia among relatives should be reflected in an increased incidence of its precursor, anacidity. All the studies of relatives analyzed as to age and the nearness of blood relationship show an increased incidence of anacidity, particularly in the two decades prior to 40, and about a double percentage of anacidity among the near relatives as opposed to distant relatives. Of a total of 174 cases in which previous gastric analyses had been recorded, 171 showed anacidity. Except in rare cases, true anacidity is found in pernicious anemia and must necessarily precede its development. Those relatives with a pernicious anemia genotype should show histamine refractory anacidity for a variable period prior to the manifestation of the anemia. Such a finding justifies at least the suspicion of potential pernicious anemia. The presence of free acid indicates that the risk of the immediate development of the anemia is small. During the last six years the author adopted a tentative scheme for the study of families in which pernicious anemia was present. He arbitrarily accepted heredity as the most important etiologic factor and considered the family as the unit of greatest potential concentration. Ten families were discovered with two or more persons having the disease, and 10 were collected from fellow internists in Los Angeles. In 18 of these 20 families the familial occurrence was proved; in 2 it was based on hearsay. Every patient was told of the familial nature of the disease and requested to have his relatives come in for a histamine gastric analysis. Many relatives refused, but 61 agreed and 10 of these showed anacidity. In the families thus studied, severe crippling pernicious anemia has since developed in 2 relatives who refused to have gastric analyses. Of the 10 anacid relatives, signs or symptoms of early pernicious anemia have developed in 4, hypochromic anemia (apparently idiopathic) in 2, 3 have normal blood and 1 cannot be located. Of the 4 cases believed to be incipient pernicious anemia, 3 were proved to be macrocytic. In 1 the diagnosis was thought justifiable owing to clearcut history of glossitis and paresthesias relieved by liver. The development of hypochromic anemia in 2 cases stresses the tendency of the apparently idiopathic form to appear in pernicious anemia families. Whether there is latent or coexistent

pernicious anemia can only be conjectured. Achlorhydria suggests the importance of knowing whether the patient has or has had a familial history of pernicious anemia. Since pernicious anemia may occur only in a single generation, it would seem important that the patients with achlorhydria be advised of this hereditary tendency so that their grandchildren may be able to make a positive statement regarding its familial occurrence. The physician should study the family rather than the patient alone. The anacid relatives should be watched for early signs and symptoms. It appears unwise to acquaint them with the early symptoms, as it would lead to the promiscuous use of liver and prevent the recognition of the early development. The insidious development of severe spinal cord damage may be prevented in many cases if the relatives of pernicious anemia patients are sought out and grouped by means of the histamine gastric analysis.

Four-Meal Diet for Diabetes Mellitus.—Margolis and Eisenstein point out that, despite technical refinements and improvements in the uniformity and stability of the new insulins, culminating in protamine zinc insulin, frequent failings of their slower actions have become apparent. Their failings are manifest in diurnal glycosuria, in the necessity for supplementary injections of regular insulin, in serious, even fatal, reactions and often in the abandonment of protamine zinc insulin in many cases in which its aid would have been most welcome. The authors were able to circumvent the obstacles by providing optimal dextrose absorption in relation to the action of protamine zinc insulin. Since the maximal depression of the blood sugar level occurs from ten to twenty-four hours after the injection of protamine zinc insulin, an adequate supply of carbohydrate was made available at the time of its greatest need by giving a liberal carbohydrate meal late in the evening, furnishing carbohydrate which is fed into the blood stream during the night slowly and continuously. This four-meal procedure yielded smooth and relatively rapid diabetic control, even in severe cases, and has in their experience successfully averted the most disagreeable features encountered when protamine zinc insulin is used. Diurnal glycosuria was apparently more readily controlled, nocturnal reactions were avoided, the need for supplementary regular insulin was obviated and the simplicity of management with protamine zinc insulin alone, that is a single daily injection, was gained. The records of 14 representative diabetic patients of various ages and with different degrees of illness are cited by the authors in the hope of stimulating a more intensive trial by others. They state that, since a single injection of protamine zinc insulin cannot be placed precisely at points around the clock where food is, the food can be placed, with a high degree of safety, where the greatest insulin action is.

Roentgen Treatment of Adrenals in Angina Pectoris.—Raab advances the theory that attacks of stenocardiac pain on effort, psychic emotion or cold are caused by anoxia of the cardiac muscle. This is largely due to acute discharges of epinephrine from the adrenals occurring physiologically under these conditions. Epinephrine exerts a specific anoxiating effect on the cardiac muscle which under normal circumstances is compensated by simultaneous dilatation of the coronary arteries. This compensatory mechanism must fail when the coronary arteries are unable to dilate adequately because of coronary sclerosis and thus an abnormally exaggerated painful degree of myocardial asphyxia results. Attempts to relieve the symptoms of angina pectoris by restricting the acute discharges of epinephrine through roentgen irradiation of the adrenals were successful in 76 of 100 patients. These patients had typical attacks of angina pectoris on effort, emotion or cold; several of the cases were of the severest kind. Sixty-two patients were entirely or almost entirely freed from complaints or, at least, considerably improved for an average of thirteen and one half months, 14 patients were moderately improved for an average of seven and one half months and 24 patients did not respond. Electrocardiographic signs of myocardial anoxia disappeared partly or completely in most of the successfully treated patients but remained unchanged in those whose complaints were not improved. The blood pressure, either high or normal, remained practically unchanged in all instances.

Hereditary Primary Glaucoma.—Stokes reports the occurrence of glaucoma in five generations. The history is as follows: William S., born in 1799, became totally blind fourteen years before his death at the age of 47. Of his two children Joe, who had normal eyes, did not marry; but Elizabeth became blind gradually while still young and for several years before death at the age of 46 she suffered from severe "neuralgic" pains in her head (absolute glaucoma). Five of her 8 children became totally blind in their early twenties. One of these, a woman of 84, is still living. The 4 children of one of these 5 affected patients are not in sympathy with the medical profession and neither they nor their children are available for examination, but of the other 4 patients having 18 children 7 were affected; 4 other children died early (at 14, 9, 6 and 2 years respectively) of typhoid. The children and the grandchildren of the 3 youngest persons of this sibship, the third generation, who did not have glaucoma did not acquire the disease. The fourth generation glaucoma came on during the second, third and fourth decades. Five of the 7 affected persons of the fourth generation married and they had 24 children, of whom 7 had glaucoma

between the ages of 15 and 31. The 6 children of the sixth generation, from 1 to 8 years of age, have been examined when their eyes were apparently normal, but they are as yet too young to have acquired the disease. The author states that hereditary glaucoma appears to result from a simple dominant and not from a sex-linked gene, as the transmission by the two sexes in the foregoing pedigree was equal. As far as he can judge from this pedigree, the chance that an offspring of a glaucomatous person would be similarly affected is about 50:50 and the chance of an offspring of a normal person appears negligible. Consanguinity did not occur in this pedigree. The reduced age of onset in the younger generation must not be taken as proof of a general tendency to anticipation of the disease. Hereditary glaucoma usually, but by no means always, appears in a chronic form. It is possible that a local or general disposition to glaucoma is inherited and the appearance of the disease depends on other factors, either inherited or acquired. The incidence of myopia was sufficiently great to suggest that the hypertension had been influential in producing refractive abnormality. There is no evidence that a beneficial outcome will result without operation. The only permanently good results were obtained in persons having one of the fistulizing operations. The best results were obtained when the operation was performed when glaucoma was still in the compensatory stage; that is, before irreversible secondary anatomic and pathologic changes occurred.

Hypertension in Young Girl Associated with Pylonephritis.—Patch and his colleagues report a case of hypertension in a girl of 12, who was found to have a unilateral atrophic pylonephritis and who has been apparently cured by nephrectomy. At the age of 18 months she had an illness lasting a few days for which a diagnosis of pyelitis was made. Since then she has had intermittent illnesses with nausea, epigastric pain and malaise. Cystoscopy was done when she was 7 because of a pyuria of four months. The right kidney urine contained clumped pus. The left kidney urine was normal. The right

kidney pelvis was lavaged with mercurochrome. Her health improved and she was well until Nov. 11, 1939, when she complained of a dull ache in her left loin. On November 13 she complained of severe occipital headache. Within the next twenty-four hours she was seized with several short convulsions, became unconscious and was admitted to the Woman's General Hospital in Montreal. There were no urinary symptoms. Cystoscopic and pyelographic studies were made showing an atrophic right kidney and a large left kidney. Her blood pressure varied between 180 and 140 systolic, and 135 and 105 diastolic. A right nephrectomy was done on December 27. The pathologic diagnosis was chronic pyelonephritis with secondary atrophy of the kidney, arteriosclerosis, hydronephrosis and chronic ureteritis. There was no appreciable change in the patient's blood pressure up to the time she left the operating table. One hour afterward it was 150; two hours after operation it was 115 systolic and 95 diastolic. During the next twenty-four hours the systolic pressure averaged 125. Following an intravenous infusion of dextrose-saline solution the blood pressure rose to 165 systolic and 130 diastolic and during the next twenty-four hours it gradually fell to 120 systolic and 90 diastolic. She was discharged from the hospital seventeen days after operation. Her blood pressure seemed to be stabilized at 90 systolic and 60 diastolic. She has remained well and without complaints. On the date of her last examination, June 4, she had gained 20½ pounds (9.3 Kg.) in weight. At this time the blood pressure was 96 systolic and 60 diastolic. The authors collected from literature 22 cases in which unilateral nephropathy was associated with hypertension and in which definite improvement followed nephrectomy. Numerous other cases have been mentioned, but with insufficient data to warrant inclusion. Of the 23 cases, 5 occurred in children of 12 or less years of age.

Gentian Violet for Pinworm Infection.—Miller and his collaborators used gentian violet tablets in the treatment of 29 school children, from 6 to 13 years of age, positive for pinworms by the National Institute of Health anal swab technic. The gentian violet was administered in ½ grain (0.03 Gm.) and ¾ grain (0.01 Gm.) tablets. The disintegration of the tablets was supposed to occur four hours after they were swallowed, thus providing the largest concentration of the drug at the site of the infection. Treatment was continued for ten consecutive days. Children from 6 to 9 years of age were given two ¾ grain tablets three times a day before each meal and children from 10 to 13 years of age were given one ½ grain tablet three times a day before each meal. One week following the completion of the treatment an anal swab was made on each patient and two others at weekly intervals. Of the 29 children who took the prescribed dosage and had three post-treatment swabs, only 3 were found still positive following treatment. The effects of gentian violet could be studied on 31 patients taking the entire prescribed dosage. Of these, 23 reported no ill effects, 2 reported slight abdominal pain, 3 slight nausea lasting only one day, 1 anorexia lasting one day, 1 anorexia lasting for several days and 1 colicky pains with nausea. No child in the age group tested and taking the prescribed dosage vomited. However, 2 children (1 and 8 years old was inadvertently given the higher dosage and the other child's dosage was halved) vomited and had anorexia. Both of these children were underweight and had poor appetites, and the smaller child was extremely nervous. The symptoms were usually so mild that treatment was not interrupted with the exception of 4 patients whose symptoms disappeared and did not return with the resumption of treatment.

Fatal Serum Reaction.—Ferguson cites the case of a boy of 6 years who was given 3 minims (0.18 cc.) of tetanus antitoxin because of many deep abrasions covered with street dirt as a result of a car accident. The antitoxin was given at 3:05 p. m., at 3:07 sodium salt of *n*-methyl-cyclohexenylmethyl malonylurea was started intravenously, and in eight minutes 5.5 cc. had been given, which was thought to be enough. There had been no premedication and the patient went to sleep quite easily with some slight twitching. There was no appreciable change in the pulse and only slightly shallower respiration. The color remained good. At 3:20 the patient suddenly began to have trouble getting air into the lungs and would not breathe, although the passage was free. The chest was held in a tightly

contracted state of full inspiration. Artificial respiration was begun and 5 minims (0.3 cc.) of epinephrine was given subcutaneously. The pulse remained strong. At 3:30 a large wheal was noticed at the site of the intradermal injection of the tetanus antitoxin. The whole flexor surface of the forearm from the wrist to the elbow was reddened and edematous. The pulse was becoming irregular and 10 minims (0.6 cc.) of epinephrine was injected subcutaneously, followed by 1.7 cc. of a 25 per cent solution of pyridine betacarboxylic acid diethylamine intravenously. The pulse improved appreciably following this. At 3:45 the pulse again became weaker and 5 per cent dextrose in saline solution intravenously was started. The patient began to take spontaneous breaths of a forced inspirational character and at 3:50 respirations were beginning to be of a more normal character. Large quantities of frothy, blood stained fluid began to pour from the lungs. The intravenous injection was stopped after 350 cc. had been given and the patient was placed in the Trendelenburg position to facilitate drainage. At 4:25 the patient's condition was much improved. Oxygen was being administered continuously through the endotracheal catheter. At 5:30 the patient suddenly stopped breathing and could not be revived. Death was considered to be due to anaphylaxis. The postmortem diagnosis after necropsy was serum reaction (accelerated) with pulmonary edema.

Transmissibility of Syphilis.—Pariser investigated the infectiousness for rabbits of the vaginal secretions and menstrual blood of 30 untreated syphilitic women. The biologic method of animal inoculation used is detailed. The author considered a result positive only when the injected material produced a syphiloma containing many spirochetes. The vaginal secretions of 7 women produced syphilis in animals. Five of these showed local cervical lesions. The clinical manifestations of the disease in these instances varied from about one week to six and one half years. The sixth positive result was obtained from the menstrual blood of a woman with secondaries who had no local cervicovaginal lesions, and the seventh from an early secondary syphilitic pregnant woman whose cervix was edematous, bluish and boggy but with no visible open lesions. How much of this cervical picture was due to the pregnancy is difficult to determine. It might have been the type of early lesion stressed by Stookey, Davies and MacDonald. Initial dark field examination revealed a few organisms which closely conformed to the universally accepted morphology of *Spirochaeta pallida* in 4 cases, slightly thicker

organisms than average but which by subsequent animal inoculation were proved to be *Spirochaeta pallida* in 2 instances while the seventh case was negative. In the absence of lesions the dark field examination in 50 per cent of the cases revealed spirochetes easily distinguished from *Spirochaeta pallida*. The case material consisted of 76 per cent early syphilis and 24 per cent late syphilis. Serologic tests for syphilis in rabbits gave, with certain modifications, high sensitivity ratings but also produced a definite percentage of nonspecific positive serologic tests. These tests should be used only as collateral evidence and only the appearance of a syphiloma containing many spirochetes should be diagnostic. The author concludes that virulent spirochetes are discharged in the syphilitic woman into the vagina in the presence of early or chronologically late (more than four years) local lesions as a relapsing phenomenon. In the absence of such lesions in the early syphilitic woman they are discharged through the menstrual blood or from an abnormally appearing cervix in which it is probable that lesions are present within the cervical os or uterus. Infectiousness through the vagina is periodically recurrent rather than continuous and depends on the presence or absence of local lesions. The physiologic secretions are not infectious. The absolute end point or the frequency of cervical relapse cannot be given, but the author states that in his cases infectious cervical relapse occurred at least six and a half years after definite onset of the disease.

Bilateral Renal and Ureteral Agenesis.—Grim cites a case of bilateral renal and ureteral agenesis in the presence of an otherwise normal urogenital system and with no demonstrable developmental defects elsewhere. The patient's mother, a 32 year old multipara, went through a normal gestation until two days before admission to the hospital, when she had abdominal cramps radiating anteriorly from both flanks. No fetal movements could be felt and no heart sounds heard. Several hours after admission she was delivered of an apparently normal

but slightly macerated stillborn fetus approximately 8 months old. Careful examination of the umbilical cord and placenta revealed no abnormalities. Necropsy of the infant revealed no abnormalities other than the absence of the kidneys and ureters. Embryologically this finding may be due to (1) failure of the ureteral bud to appear, (2) failure of the ureteral bud to develop or grow cephalad into the nephrogenic cap, (3) degeneration of the ureteral bud from any cause before it has contacted the nephrogenic cap, (4) failure of the nephrogenic cap to appear, and (5) degeneration of the nephrogenic cap after its appearance and (6) defective germ plasm. The author points out that Ranier's contention that development of the metanephrogenic blastema depends on the stimulus evoked by cephalic progression of and contact with the ureteral bud seems to be borne out by the observations in his case. He believes the associated pathologic changes may be attributed to asphyxia in utero.

Sodium Sulfapyridine Intramuscularly.—Hall and his associates observed no local irritation or tumefaction after many deep intramuscular administrations of sulfapyridine. The clinical effects were equal to those obtained by other routes. Blood levels of from 3 to 10 mg. per hundred cubic centimeters were promptly obtained. Once the level is reached it can be maintained for longer periods than when given intravenously. Gastrointestinal reactions are almost entirely avoided, nausea does not occur and vomiting is seldom observed. This route may be found to be a safe alternative for intravenous injection in old persons with tortuous and sclerotic vessels, in infants, children and women with inconspicuous veins, or in persons with fat arms. The authors used a 33½ per cent solution of sulfapyridine in sterile water, injecting it deep into the gluteal or thigh muscles. No material must be deposited in the subcutaneous tissue through the needle tract either on injection or during withdrawal of the needle. Each cubic centimeter of the solution contains 0.33 Gm. of the drug. From 6 to 10 cc. was given as the first injection and was followed by 3 cc. every four hours until the temperature had been normal for twenty-four hours. Thereafter the dose was reduced by one half and continued for

the next five or six days. This route has been used for pneumonia, undulant fever, appendicitis with peritonitis, abscesses, pyelitis, typhoid, gonorrhea, sinusitis and many other diseases. The authors state that the clinical results parallel those obtained by orally administered sulfapyridine.

Placenta Accreta.—Bosshardt states that placenta accreta is being seen and recognized more frequently as the most serious complication of the third stage of labor. The condition results from a partial or complete absence of decidua basalis. Placenta

accreta must never be confused with the rather common simple placental retention seen in hour-glass constriction or from some failure of the normal separating mechanism of a healthy placenta in a normal uterus. Since this condition can never be detected before delivery, it should be constantly kept in mind after the second stage of labor. Treatment depends on prompt recognition. Early hysterectomy is the accepted treatment, preceded and followed by blood transfusion, if indicated, and the usual supportive agents for shock. Manual extraction of densely adherent placentas by hand, with placental forceps or by curet is extremely dangerous and predisposes to fatal hemorrhage or puncture of the uterus. In 11 cases treated by supravaginal hysterectomy with no attempts at extraction of the placenta there were no deaths. There were 6 deaths among 30 cases in which abdominal hysterectomy after partial manual extraction was employed. Manual extraction or curettage without hysterectomy for 31 cases resulted in 20 deaths. The combined mortality of the treated series reported in 1931 showing 86 cases with 32 deaths was 37.2 per cent. The author's cases bring the total to 101. His patient, even after procrastination for nine days and adopting the hazardous method, unknowingly, of partial manual extraction, recovered after a subtotal hysterectomy.

Ruptured Ulcers in Infants.—Quinn reports 3 fatal cases of ruptured gastrointestinal ulcers in infants. Two of them occurred during a year when there was an epidemic of infectious diarrhea. One of these, the author believes, can be said to have occurred from this cause. The following diagnostic criteria stand out: First, pneumoperitoneum was determined by roentgen study, yet this failed in the first case so examined. The other diagnostic point was that abdominal distention occurred suddenly in an otherwise healthy infant. The distention was symmetrical and had the feel and appearance of an inflated round bag. The principal features of the first case were an infant doing well who vomited following a feeding and four hours later vomited again. The abdomen was markedly distended, giving the appearance of an inflated ball. Attempts to relieve distention were unsuccessful. Respiratory distress, cyanosis and shock were present. In the second case, because of sudden vomiting, abdominal distention and shock, the presumed diagnosis was ruptured gastrointestinal ulcer, but because pneumoperitoneum was absent on roentgen study the preoperative diagnosis was intestinal obstruction. The operative observations proved the first premise correct, yet no pneumoperitoneum was present. The third infant died five days after operation. The anatomic diagnosis was primary, perforated acute peptic ulcer (clinical), generalized fibrinous purulent peritonitis and bilateral bronchopneumonia. The cause of death was bronchopneumonia.

Pyelitis of Pregnancy and Its Management.—According to Mussey and Lovelady, among 5,960 deliveries at the Mayo Clinic 117 were complicated by pyelitis. Four others have been encountered since the introduction of sulfanilamide. Seventy-two of the patients were primigravidas and forty-five multigravidas, bearing out some previous reports that pyelitis occurs more frequently among the former. There were ninety-two instances of antepartum and twenty-five of postpartum pyelitis. Postpartum pyelitis was usually of mild degree and did not exhibit the usual symptoms of pyelitis of pregnancy. Previous infection of the upper part of the urinary tract plays a part in the recurrence of pyelitis in subsequent pregnancies; however, only twelve of the present patients gave a history of pyelitis prior to the first pregnancy and none gave a history of urinary infection in childhood. The data of the 117 cases do not confirm the assertion that pyelitis increases the hazard of pregnancy. There were four spontaneous abortions and two premature labors. Labor was induced because of pyelitis in seven cases, but not before viability. One of 117 patients died. Acute pyelitis was rarely the cause of preeclamptic toxemia or eclampsia among the series discussed. Although pyelitis is not a common complication of pregnancy it occurs with sufficient frequency to necessitate alert diagnosis and treatment before permanent renal damage occurs. Whenever pus is found in a specimen of urine during periodic prepartum examination a specimen of urine obtained by catheterization should be examined for pus, for pyelitis without subjective symptoms may be present. The 121 patients have been divided into four groups. Group 1 received large quantities of fluids and usually one of the urinary antiseptics, group 2 was treated by ureteral catheter drainage, group 3 was given one of the various mandelic acid preparations and group 4 includes the four patients given sulfanilamide. The results of administering large quantities of fluid to sixty-four patients were uniformly good and indicate that in more than one half of the cases pyelitis of pregnancy will respond favorably to forced fluids and rest in bed. These measures were most effective when applied early in the course of the disease. In group 2, forty-eight patients, there were acutely ill patients who failed to respond to the treatment outlined in group 1, and indwelling catheters were inserted for adequate drainage of the renal pelvis. From 1924 to 1933 ureteral drainage was used in approximately 57 per cent of patients with proved pyelitis of pregnancy. Since 1933 this treatment has been employed in approximately 19 per cent of the cases. When pyelitis of pregnancy is recognized and treated in its early stages, a majority of patients will recover following a regimen of rest in bed, sedatives and forced fluids. The effect of this management has been a continuing decrease in the number of patients requiring ureteral catheterization. Since the advent of chemotherapy, this will no doubt become still less. The only death of the entire series occurred in this group. Mandelic acid was used for the five cases of group 3, and the response to treatment was uniformly good. The response of the four patients of group 4 to sulfanilamide was good. Further observation may indicate the advisability of employing azosulfamide or other allied products. The average duration of fever and hospitalization of the groups of patients was, respectively, fever 3.6, 6.8, 3.0 and 5.0 days, and hospitalization 10.7, 10.8, 14.0 and 13.0 days.

Cyclic Ulcerative Vulvitis and Stomatitis.—Jones points out that numerous cases of coexisting oral and genital ulceration have been reported but that only 3 of these seemed to have any relation to menstruation. He reports the fourth case of such an association. The clinical similarity between the genital and oral ulcers is striking, and so it is probable that the ulceration of the two areas has the same pathology. Since the original observation by Neumann in 1895 the etiology of their association has excited much discussion and at present there are three main theories: that of an acute infectious dysfunctions, and that of angioneurotic gangrene due to ovarian dysfunction. The first two theories fail to become established. The ovarian dysfunction theory becomes feasible as in the cases reported and in the author's case the lesions were dependent on the menstrual cycle. The condition was associated in some weeks before menstruation, lasting over the period but ceasing after menstruation, while the oral lesion occurred from one to two days before, during or after menstruation. The striking appearance and disappearance of the lesions with a regular relation to menstruation is highly suggestive of an endocrine changes (proliferation of the stratum germinativum, with

increase in the number of young epithelial cells in the basal philic zone of the epithelium, and this is associated with occasional mitosis and a definite leukocytosis and hyperemia) in the vagina related to the hormone changes of menstruation. The fact that the time of these changes coincides with the ulcerative phase in the condition under discussion further enhances the endocrine basis. Since these ulcers appear at the premenstrual period when the secretion of estrogen is highest and disappear at the postmenstrual phase when it is lowest, a deficiency of estrogen is probably not the etiologic factor, and it is unlikely to be due to an excess of estrogen as the phenomena disappear during pregnancy. On the other hand, the absence is present during the stage when the pituitary normally lessens its production of gonadotropic substance and its reaches its maximal concentration. Likewise during pregnancy (as in 1 case) when the anterior pituitary hormone attains its highest degree of activity there was a spontaneous disappearance of the ulceration. Therefore it seems reasonable that a lowered pituitary activity may cause the condition. Ziserman reported great improvement in his case after administration of an anterior pituitary preparation. In the author's case complete relief was obtained with gonadotropic substance, while the anterior pituitary preparation was given was she completely free from both ulcerative lesions. Though the therapeutic trials suggest that deficiency of gonadotropic substance is the basic cause, the true underlying factors must still remain obscure. It is probably due to some systemic condition associated with an imbalance between various hormones. This is plausible, as the ulceration occurs at a time when there is a change in the cycle and when a harmonious cooperation between the hormones is necessary. Therefore any endocrine imbalance that occurs will reflect itself on the changes in the genitalia and general systemic system, and this will be more likely to occur in individuals whose vasodilatory system is easily affected, resulting in ulceration of the mucous membrane. The condition described is a definite syndrome and can be recognized as such when other factors (infection and anemia) have been eliminated. The disease differs from ulcer vulvae in that it is recurrent and rebellious to treatment and appears to be a systemic condition dependent on some dysendocrinism.

Strains of Actinomyces from Normal and Actinomycotic Mouths.—In an investigation of patients with actinomycotic lesions in the cervicofacial region, Sullivan and Goldsworthy were impressed by the frequency with which the theory of endogenous infection. They have since examined material from the mouths of subjects with no history or clinical signs of actinomycosis and pus from cervicofacial lesions. From these they isolated anaerobic strains similar to *Actinomyces bovis* (Wolff and Israël) and compared these apparently non-pathogenic strains with those obtained from the lesions and with a strain from a subcutaneous abscess secondary to pulmonary actinomycosis. Five strains were isolated from periodontal

pockets (more than 100 were examined) and one from a carious tooth (twenty-four specimens were examined). Five other strains were isolated from lesions situated near the angle of the mandible, and one relatively old strain was obtained from the lesion secondary to pulmonary actinomycosis. In a comparative study which included fermentation reactions, these two groups of strains were identical. The results support the conclusions of other workers that the micro-aerophilic *Actinomyces* of Wolff-Israel is to be regarded as part of the normal flora of the oral cavity, at least if local dental conditions (caries and periodontitis) are accepted as practically universal. The authors' observations at dental clinics suggest that the acute form of actinomycosis is a not infrequent sequela to surgical manipulation of the mouth parts, especially the teeth. Therefore they believe that the organism leads a saprophytic existence in the mouth and invades the tissues only when conditions are rendered favorable, as by injury.

Pneumoconiosis in Coal Trimmers.—Gough states that in the last ten years fifteen coal trimmers have been encountered in routine postmortem work at the Cardiff Royal Infirmary. Three of these had previously been coal miners, but of at least five pneumoconiosis was the main cause of death. Coal trimming is the shifting and storing of coal on board ship in such a way as to make the vessel seaworthy. Most of the work is done in the ship's hold in an atmosphere thick with coal dust. The author's experience in Cardiff with steam coal leads him to conclude that exposure to these high concentrations for many years may lead to serious and sometimes fatal pulmonary fibrosis. One of the five men whose death was attributable to pneumoconiosis had a superadded pulmonary tuberculosis, and another had a limited carcinoma of the lung but the fibrosis and not the tumor was the cause of death. All in this group had been trimmers for more than twenty-five years. Three of the other men had severe pulmonary fibrosis but it was not the direct cause of their deaths. All had been trimmers for more than thirty years. The pulmonary fibrosis was slight in the other four men. They had been employed as trimmers for forty, thirty, seventeen and nine years, respectively. Like the pneumoconiosis of other industries, that of the coal trimmer shows fibrosis of two types—the discrete nodular and the massive or conglomerate. The massive type was present in the seven most severe cases. Microscopically the most prominent feature in the smallest nodule was the presence of abundant carbon. In the areas of massive fibrosis the parenchyma of the lung was completely replaced by dense fibrous tissue. The authors state that some clinical support to their observations has been furnished by Bathgate, who in his panel practice found clinical and x-ray evidence of pneumoconiosis in forty-four trimmers, eleven of whom were regarded as unfit for work owing to their pulmonary condition, and by Collis and Gilchrist, who reported in 1928 that coal trimmers in Cardiff often showed clinical and x-ray evidence of silicosis.

Sulfanilamide and Serum for Gas Gangrene Infections.—Singer investigated the protective power of sulfanilamides combined with antitoxic serum against experimental *Clostridium welchii* and *Clostridium septicum* infections. He also tried to increase the resistance of animals (mice) against the effects of the toxin with desoxycorticosterone. In a number of mice infected with soil suspensions and given a sufficient amount of the drug to cure an infection produced with pure culture of *Clostridium welchii*, postmortem studies revealed *Clostridium welchii*. This may mean that strains of *Clostridium welchii*

differ in their susceptibility to the drugs or that mixed infection reduces their efficacy. Four strains of *Clostridium welchii* were used. Infection was produced by injecting subcutaneously into the tissues of the back twenty-four hour cultures of the particular anaerobe. Five equal doses of the drug were administered by stomach tube, two, four, seven, twenty-four and thirty-one hours after infection. The antitoxic serum was injected two hours after infection and immediately after the first dose of the drug. Considerable variation was encountered with different batches of mediums and different strains of organisms. Parallel experiments with groups of 4 mice show that more recently isolated strains seem to be more resistant to the drugs than the old laboratory strain S 107 used. The views of Stephenson and Ross that infections with strongly toxigenic strains were less responsive to chemotherapy were not substantiated as strain S 107, the most toxic strain, was the most susceptible to treatment. Tests with *Clostridium histolyticum* showed that sulfanilamides were completely inactive against it. The different sulfanilamides were about equally effective against infections with *Clostridium welchii* S 107 and with *Clostridium septicum*. Accordingly, only sulfanilamide and sulfapyridine were tested in conjunction with serum therapy. The amount of antitoxic serum administered was by itself inadequate to inhibit the course of the infection. Infections with multiples of one fatal dose were cured with relatively small quantities of drug combined with an amount of serum that by itself would be quite ineffective. This suggests that a similar form of therapy might be of considerable value in treating gas gangrene infections in the human being. The action of sulfanilamide drugs on *Clostridium septicum* infections was much weaker than on those of *Clostridium welchii*. However, much better results were obtained with the combined treatment. It seems that the better results with sulfanilamides plus serum treatment of *Clostridium septicum* infections are due, at least partly, to a kind of double action of the sulfanilamides on *Clostridium septicum*, while in *Clostridium welchii* infections the action of the drug limits itself to bacteriostatic and growth inhibiting effects. Some other mechanism not investigated in these experiments may be concerned. An attempt to treat fatal *Clostridium oedematiens* infections with a combination of drug and serum failed, as did treatment with drugs alone. Experiments with garden soil suspension infection and then treatment with the sulfanilamides and serum showed that all the deaths (11 of 20 mice used) were due to some cause other than the infection. A few experiments on mice showed that if treatment was delayed for from four to five hours after infection the possibility of cure was greatly lessened. In determining the effect of desoxycorticosterone against the toxin of *Clostridium welchii*, experiments were performed to show the action of the hormone against an immediately fatal dose of toxin and its influence on a chronic intoxication. Eight mice were given two daily subcutaneous injections of desoxycorticosterone (0.1 mg. in 0.1 cc. of sesame oil). On the second day 0.05 cc. of crude *Clostridium-welchii* toxin (one fatal dose) was injected intraperitoneally. Eight mice, injected with toxin and pure sesame oil, served as controls. Of the mice treated with the extract 6 survived and only 1 of the controls survived. In another experiment 6 mice were given two daily injections of desoxycorticosterone before the *Clostridium welchii* toxin was administered. One third of a fatal dose of the latter was then given on five successive days and the administration of desoxycorticosterone was continued during this period. All the mice so treated survived, while only 2 of the control mice, injected with toxin and sesame oil, survived. Further research on the increase in resistance from desoxycorticosterone is indicated.

*Tuberculosis in Young Persons. O. Chiari.—p. 608.

Infectiousness of Icterus.—According to Lainer the only one form of jaundice in which the etiology is clearly established is Weil's disease caused by *Spirochaeta icterogenes*. The literature contains numerous reports of epidemics of jaundice in which the epidemic character was construed as evidence of its infectious nature. In other epidemics alimentary intoxication was cited as chief etiologic factor. Brugsch studied an epidemic of this type but was unable to detect a pathogenic organism. He suggested that these alimentary intoxications develop as the result of fermentative processes in the food, the fermentation producing dyspepsogenic and icterogenic substances which impair the liver. Other investigators raise the objection that the failure to detect a pathogenic organism does not exclude an invisible virus as possible cause. The large group of organisms belonging to the *Bacterium typhi* type have been connected with epidemics of jaundice, because of parallel appearance of the two, but investigations along this line have remained negative. As to sporadic or catarrhal icterus, although history here often reveals disorders of a toxic origin, many attempts have been made to ascribe to it an infectious cause. Icterus catarrhalis has been classified into three etiologic groups: (1) icterus simplex levis resulting from duodenitis with swelling of the papilla vateri, (2) icterus simplex duodenalis resulting from specific cholangitis and (3) icterus simplex hepatis resulting from diffuse parenchymatous impairment of liver by an infectious agent. Certain infectious diseases may play an icterogenic role. Attempts have been made, particularly by Andersen, to transmit catarrhal icterus to experimental animals. He obtained positive results in animal to animal and in man to animal experiments with the transmission of blood and of duodenal juice. Andersen's results induced the author to attempt transmission of catarrhal icterus from patients to animals by the feeding of duodenal juice and by blood transfusion, but extensive animal experiments failed to produce positive results. After several self experiments had remained negative the author made blood transfusions (300 cc. each) from fifteen patients with typical catarrhal icterus to persons without icterus. The duodenal juice was removed from these patients and introduced into healthy subjects. The serum bilirubin, the galactose elimination, the urobilinuria, the azorubin elimination in the duodenal juice were carefully examined in all the recipients of blood and duodenal juice, but none of them showed signs of hepatic impairment or of icterus. On the basis of these investigations the author concludes that the so-called icterus catarrhalis, whether sporadic or endemic, is the manifestation of a serous hepatitis produced by endogenic or exogenic toxins, but not by a specific icterogenic organism.

Tuberculosis in Young Persons.—Chiari stresses the susceptibility to tuberculosis during the puberal age and the importance of early diagnosis. The early recognition is difficult because the onset is often insidious. The general condition may be only slightly impaired and emaciation be entirely absent. Tuberculosis may simulate other disorders, for its manifestations are extremely varied. Every prolonged disorder in young persons should make the examiner think of tuberculosis. The family history is the first factor to be investigated. A case of open tuberculosis in the environment necessitates a careful search for tuberculosis. For this purpose three methods are of especial importance: the tuberculin reaction, x-ray examination and the demonstration of tubercle bacilli. If these methods are correctly utilized, it generally will be possible to detect a tuberculosis which requires treatment. The first aim of the treatment is the improvement of the patient's general condition, so as to strengthen the defense powers of the organism. Rest, fresh air and good food are of primary importance, while collapse therapy may be necessary in pulmonary tuberculosis and orthopedic measures in case of skeletal tuberculosis.

*Endometrial Implants in Small Intestine and in Navel: Case. A. Aronsson.—p. 43.

Differential Diagnosis in Gastric Hemorrhage.—Ask-Upmark discusses the diagnostic difficulties involved in determining the true cause of massive hematemesis. The clinical picture may be due (1) to a local process in the upper digestive tract, such as ulcer and carcinoma, (2) to stasis in the region of the portal vein, such as biliary cirrhosis, in which the esophageal varices constitute the hemorrhagic outlets, or thrombosis in the portal or splenic veins and (3) to a systemic disease with tendency to bleeding, such as malignant nephrosclerosis. Carcinoma rarely leads to excessive bleeding, yet, if accompanied by dyspepsia of recent date at the cancer age level, needs to be promptly examined roentgenologically despite the bleeding. Splenic thrombosis favors male subjects averaging between 20 and 24 years but is relatively rare, yet the spleen needs to be kept under constant observation during the course of the disease, as splenic enlargement may temporarily be abated, the blood finding an outlet through the ruptured ventricular branches of the splenic vein. The greatest diagnostic difficulties inhere in differentiating gastric ulcer from liver cirrhosis. Here laboratory confirmations of hepatic insufficiency afford no positive proof of cirrhotic involvement, as the same confirmations may be obtained for ulcer. The Takata-Ara test is always negative in ulcer and often, but not always, positive in biliary cirrhosis. Ultimately, differential diagnosis must rely on purely clinical analyses and morphologic methods of examination, such as the roentgen rays and the various forms of endoscopy. The fact that both pathologic processes are not infrequently found coexistent complicates the situation still further. In gastric hemorrhage due to malignant nephrosclerosis, an increase of nonprotein nitrogen is inconclusive for renal insufficiency as long as blood is present in the digestive tract.

Endometrial Implants in Small Intestine and Navel.—Aronsson reports the case of a woman aged 43 with endometrial implants in the small intestine which were associated with endometrial implants in the navel. The patient was hospitalized for acute intermittent spasmodic pain in the lower part of the abdomen. The history of the case disclosed that for three years a small nodule situated on the umbilicus would swell, become painful and bleed with every onset of the menstrual flow. After roentgenoscopy surgical intervention was done for ileus. The causative agent of ileus was found to be a cicatricial contraction in that portion of the small intestine in which the ileum begins, with a considerable narrowing of the lumen, which suggested cancer. A portion of the intestinal area was resected. Microscopic examination established endometriosis. The patient made an uneventful recovery. Pains no longer occurred at menstruation. However, the umbilical nodule when last seen showed a threatening enlargement and suggested the necessity of extirpation. Endometrial implants are defined by the author as tissue growths presenting the same microscopic picture as the mucosa of the uterus but occurring outside its distinctive domain. Endometrial implants on the surface of the intestine are usually asymptomatic and encountered at operation. Endometrial implants in the ileocecal area are usually diagnosed as chronic appendicitis. Spread by infiltration, they frequently cause stenotic complications and invite the diagnosis of carcinoma. Since it is almost impossible to establish a differential diagnosis from cancer, endometrial implants in the small intestine require operation. Endometrial implants in the navel are likewise very common. The clinical aspect is that of a nodule of relatively large or small size presenting swelling, pain and often bleeding. After the cessation of the menstrual flow, the navel dries and leaves an encrustation. The phenomena recur at the next cycle. The author briefly discusses the kinds of implants, their microscopic structure, their shape and appearance, the procedure of their diffusion, their usually benign evolution and the observations of previous investigations, and presents bibliographic references.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE
DEPARTMENT, JULY-DECEMBER 1940

Titles have been listed or Abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1931. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "SS," Student Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2371.

respiratory, from spores of rust and smut on grain, [Waldrott] 1401—ab
sensitivity to acetylsalicylic acid (aspirin) [Gardner] 1485—ab
sensitivity to digitalis, 1122; (reply) [Abramowitz] 1909
Sensitivity to Food: See Food; Milk
sensitivity to heat, 402
sensitivity to liver preparations, 1121
sensitivity to May fly (Ephemera), [Figley] 250—ab
sensitivity to rubber sponge powder puff, [Hollander] *2271
sensitivity to sisal fiber or hemp, 479
sensitivity to soap, substitutes suggested, [Jordan & others] *1001; 2018
sensitivity to wool fat, 76
serum arthralgia, 2301
serum collapse, symptomatic treatment, [Von Koss] 257—ab
serum, in diphtheria, [Hertel] 259—ab
serum, judging boy scout's sensitivity to, 479
serum reaction (fatal), [Ferguson] 2312—ab
serum sickness, hypertonic dextrose for, [Stout] 2213—ab
treatment, Allergic Extracts-Mulford, 1999
treatment, desensitization to hop plant 555
treatment, histaminase (Torantil T360) [Corper & Cohn] *30; [Goldberg] *429; [Greenbaum] *847; (Council report) 1019; 1023—E; [Alexander] 1923—ab
treatment, histamine, [Alexander] 1923—ab
treatment, hydrochloric acid intravenously 635
treatment, hypossensitization, 321
treatment, mecholyl desensitizes to wheat, [Pearson] 643—ab
treatment, potassium chloride, [Spain] 251—ab; (ineffective) [Furstenberg] 1404—ab
Tuberculo: See Tuberculosis, allergy
ANAPHYLOTOXIN, Dale-Laidlaw theory, 1023—E
ANASTOMOSIS: See Intestines surgery; Ureters surgery
ANATOMY, chromatic brain specimens for teaching, [Darrall] *1630
Defects: See Abnormalities; Deformities (cross reference); Monsters
in medical education, 1938—SS
Morbid: See Pathology
ANATOXIN: See Toxoid (cross reference)
ANCYLOSTOMIASIS: See Hookworm Infestation
ANDERSON, HATTIE, abortionist sentenced, 1648
ANDREE Eye Lash and Brow Colure, 401—BI
ANDRIEU, JOSEPH, advocates intravenous alcohol for alcoholic addicts, 1040
ANDROGENS, action on adrenals, [Selye] *2250
testosterone propionate for cryptorchism, [Zelson] 1752—ab
testosterone propionate for discharging breast, 1122
testosterone propionate for hypogonadism in boy 17 years old, 2017
testosterone propionate for major menstrual molimina with hypermenorrhea, [Greenblatt] *120
testosterone propionate for menorrhagia and metrorrhagia, 75
testosterone propionate for premenopausal uterine bleeding, 954; [Mazer] 1665—ab; [Huffman] 1916—ab
testosterone propionate for prostate hypertrophy, [Bühler] 258—ab
testosterone propionate injection effect on spermatozoa number, [Kreutzmann] *1424
therapy in gynecologic practice, [Huffman] 1916—ab
ANEMIA: See also Anemia, Pernicious
achrestic, etiology; prognosis, [Israëls] 339—ab
aplastic, 1657
arterial, in children, [Hammé] 494—ab
Cerebral: See Brain anemia
diagnosis, sternal puncture, [Nordenson] 260—ab
erythroblastic (Cooley's), [Conferences on Therapy] *300
essential juvenile, due to iron deficiency (chlorosis), [Alsted] 2226—ab
etiology, cumulative carbon monoxide poisoning, [Beck & others] *1
etiology, sulfapyridine, [Moeschlin] 1410—ab
etiology, unsuspected renal calculus, [Gutierrez] 1313—ab
examination and standards under Selective Service, 1538; (modified) 1726
hemolytic congenital, 1042
hemolytic, from sulfanilamide, [Carey] *928; [Spence] 252—ab
hemolytic, in infants, [Abt] 2027—ab
hemolytic-ictero, with gallstones in children, [Fitz-Hugh] 235—C

ANEMIA—Continued
hyperchromic, in beauty parlor operator, 633
Hypochromic: See Plummer-Vinson Syndrome
infantile, constitutional, [Hjorth] 2032—ab
macrocytic, treatment, [Conferences on Therapy] *39
megalocytic, in ileitis, [Plum] 420—ab
sickle cell, nervous system in, [Hughes] 1310—ab
splenic (Banti's disease or syndrome?) 1456—E
splenic (Banti's), pathogenesis, [Thompson] 1401—ab
splenic (Banti's), splenectomy in, [Barg] 566—ab
treatment, sternal transfusion of marrow, [Morrison & Samwick] *1708
ANEMIA, PERNICIOUS, gastroscopic study, [Carey] 161—ab
prevention by gastric analysis in patient's relatives, [Askey] 2310—ab
spinal cord degenerations or reactions to sacral anesthesia? 322
treatment, liver; erythrocyte count before and after, [Middle] 1129—ab
treatment, Liver Extract N.N.R., (Lilly) 1197; (Abbott) 1279; (National Drug) 2281; (Lederle) 2281
treatment, liver extract affects basal metabolism, [Bocuzzi] 1928—ab
treatment, liver preparations, sensitivity to, 1121
treatment, liver preparations; ventriculin, [Conferences on Therapy] *39
ANESTHESIA, abdominal block with procaine and corbalis plus general, for upper abdominal surgery, [Tovell & Hinds] *1690
American Board of Anesthesiology, Inc., (increases fees) 469; (scope, etc.) *726
A.M.A. Session on, 64—OS
choice in compound fractures, [Eloesser] *1848
choice in gunshot wounds of abdomen, [Rippon] *1763
choice in surgery of knee, [Bohlman] *2243
choice in surgery of obstructing prostate, [McCarthy] *1798
effect on blood pressure, 231
explosion danger, floor furnace (Coleman heater) in operating room, 1040
hyperthermia after, [Burford] 1831—ab
intravenous, especially with amylal sodium or pentothal, 73; (correction) 229
liver injury from chloroform vs. ether and cyclopropane; plasma prothrombin levels, [Cullen & others] *991
local, injecting in infected area, 1393
McCurdy Model Gas Machine, 2082
peracine hydrochloride block (Vishnevsky's) [Shnaper] 1836—ab
procaine block in shoulder conditions, [Steinbrocker] 2025—ab
rectal, with avertin, 73; (correction) 229
sacral, spinal cord degenerative lesions from, 322; (reply) [Squires] 955
divinyl ether (vinethene) [Livingstone & others] *1353
ANESTHETISTS, Association of, protest against nurse-anesthetists, London, 1818
role in anoxia, [Waters] *1687
role in bronchopneumonia, [Waters] 1830—ab
role in postoperative atelectasis, [Mousel] *899
ANEURYSM, abdominal aorta, surgery for, [Bigger] 2213—ab
dissecting, from unusual muscular effort or from trauma 9 years ago, 635
splenic, [Sperling] 1925—ab
ANGER, temper tantrum, 427—ab
ANGINA, agranulocytic, from causal, [McGovern] *1359
agranulocytic, from sulfanilamide? 150
agranulocytic, in sisters, [Samson] 260—ab
agranulocytic, Schultz syndrome, [Drevermann] 969—ab
agranulocytic, use of terms neutropenia, granulocytosis, agranulocytosis; also treatment, [Conferences on Therapy] *126
Vincent's, treatment, [Richards] *502; (nicotinic acid) [King] 969—ab
ANGINA PECTORIS, etiology, slow carbon monoxide poisoning, [Beck & others] *1
military service and [Holzmann] 1233—ab
pain induced by breathing oxygen and ingesting food, prevented by atropine and vagal section, [Gilbert & others] *1962
treatment, beverage alcohol, [Helwig] 85—ab
treatment, Dropanex (Desympatone), Council report, 1455
treatment, eupaverine, a morphine derivative, [Depfelf] 259—ab; (correction) 470
treatment, roentgen irradiation of adrenals, [Raab] 2311—ab
ANGIOMA: See Hemangioma
ANGIOTONIN, blood pressor substance, [Chaset] 1847—ab; 1889—E
ANIMALS: See also Birds; Cattle; Dogs; Foxes; etc.
alkali disease in horses, cattle, swine and poultry from selenium in food, 2001—E
children having been reared by, 1245—ab
dead, danger from rabies in, 405
dead, danger of postmortem on, 1675—ab
ANKLE Clonus: See Reflex
fracture, [Aldredge] *2136

SUBJECT INDEX

JOUR. A. M. A.
Dec. 28, 1940

- ANKYLOSIS: See Hip Joint
ANKYLOSTOMIASIS: See Hookworm Infestation
- ANNUAL Conference; Congress: See American Medical Association
- ANOMALIES: See Abnormalities
- ANOXEMIA: See Blood oxygen
- ANOXIA: See Oxygen deficiency
- ANTACIDS: See Peptic Ulcer, treatment
- ANTERIOR Pituitary-Like Substances: See Gonadotropins
- ANTERON, Schering Corporation (Council report), 1938
- ANTHEL Tablets, 631—BI
- ANTHRAX, danger from postmortem on dead animals, 1675—ab
- ANTHROPOLOGIST; Dr. Sellman, 1903
- ANTIBODIES: See also Pneumonia
serum study to control serum dosage, [Taplin] *1677
- ANTIDERMATITIS Factor: See Vitamins B₆
- ANTIURETIC Hormone: See Diuresis
- ANTIGENS, Lipoid; Substitute: See Echinococcus
- ANTIMONY, dangers from chipped enamelware, 798; (reply) [Wallace] 1823
- Potassium Tartrate: See Malaria, therapeutic
- ANTISEPTICS: See also Bactericide; Disinfectants; Sterilization, Bacterial
alcohol, ether and acetone, 1217
Council discusses, 133; 2083
"staining," action of, 1476
- ANTITOXIN: See also Staphylococcus; Tetanus
Ferry's: See Meningitis, epidemic
International standards, 870
- ANTHRUM: See Scarlet Fever
- ANURIA: See Maxillary Sinusitis
- ANUS: See also Rectum
peritonitis and external hemorrhoids, 1216
Pruritus: See Pruritus
- ANXIETY Attacks: See Neurosis
- AORTA, Abdominal: See also Aneurysm
abdominal, complete occlusion, [Gross] 1130
- Syphills: See Aortitis, syphilitic
- AORTIC BODIES, function, [Schmidt] 1923—ab
- AORTIC VALVE insufficiency (syphilitic), prognosis in, [Kampmeier] 1579—ab
- AORTITIS, syphilitic (incidence), [Gelperin] 1577—ab; (prognosis) [Kampmeier] 1579—ab
- APOMORPHINE Treatment: See Alcoholism
- APPARATUS: See also Diathermy; Flasks; Inhalation; Instruments; Metabolism, basal; Roentgen Rays; Splints; Sunlamps; etc.
blood bank, at Johns Hopkins Hospital, [Ravitch] *171
for Drying Blood: See Blood, dried
market value, 1817; 2293
- APPELLA Apple Crisps, 1635
- APPENDICITIS, acute, [King] 807—ab
acute, in children, [Miller & others] *1239
campaign against, Georgia, 1647
complications, peritonitis, sulfanilamide in [Ravdin] 163—ab
complications, peritonitis, treatment, [Stafford & Sprong] *1242; [Barrow & Ochsner] *1246; [Schmidt] *1360
diagnosis, referred pain in lung pathology, 1104—E
etiology, pinworm infestation, concomitantly in same family, [Mayer] *1009
in aged, [Stalker] 569—ab
incisional hernia, 955
mortality, in Johns Hopkins Hospital, [Stafford & Sprong] *1242
mortality (reducing) after continuous gastrointestinal decompression, [Vard] 1231—ab
Van Rump (Richard) on cure of, in *Journal of Drugless Physicians*, 786—E
with complete situs inversus viscerum, [Lawrence] 1229—ab
- APPENDIX, foreign bodies, pinworm infestation, [Mayer] *1009
- APPLE crisps: Appella, 1635
- APRICOTS, chopped, Beech-Nut Brand, 535
- APTITUDE TESTS, predictive value at Vanderbilt U., 1144—SS
- ARAKAWA Reaction: See Milk, human
- ARBOLONE, Tablets, 631—BI
- ARCH: See Foot
- ARCHIVES: See American Medical Association
League Against Tuberculosis, 871
Radiologic Society, 547
Society of Medical Psychology and Psychoanalysis, 628
- ARGON, fluorescent lighting with, 238
- ARIBOFLAVINOSIS: See Riboflavin deficiency
- ARIZONA, diabetic morbidity survey, [Joslin] *2033
- ARMOR, in European War, 626; 870; 1725—E
- ARMS: See also Extremities; Fingers; Hand; Shoulder
Amputation: See Amputation
elephantiasis (surgical) or recurrent breast cancer, 1477
extended arm pressure sign of breast malignancy, [Rees] *683
- ARMSTRONG, CHARLES, transfers pollomyelitis to eastern cotton rat, 221—E; 1802—E
- ARMSTRONG, D. B., comment on A.M.A. scientific exhibit, New York Session, 1282—E
- ARMY: See also European War; Soldiers; Veterans; War
British, (mobile x-ray unit for) 69; (detecting tuberculosis in recruits) 546; (examining radiography to detect pulmonary tuberculosis in recruits) [Cooper] 1492—ab
Canadian recruits, routine chest x-ray, [Jones] 1664—ab
U. S.: See also Medical Preparedness
service) 1201; (wishes reprints) 1649
U. S. (Base Hospital Camp Grant Reunion Association) 143; (Medical Field Service School graduates) 1025; (statistical study of mobilization in various wars: 1776-1917) 1807; (new hospitals) 1891; 2009; 2091;
- ARRHYTHMIA: See also Auricular Fibrillation; Auricular Flutter
cardiac, drug therapy, [Lery] *848
No. 19-D, Indian Herbs Company Remedy
- ARSENIC, cause of, 1118—BI
[Goeckerman] 1750—ab
dermatitis from cigarettes, [Barksdale] 653
—ab; *672
insecticide in cow's milk cause of abortion in women? 2106
peripheral neuritis, synthetic vitamin B₆ and poisoning, aplastic anemia, 1657
Treatment: See Malaria, therapeutic
- ARSPHENAMINE: See also Neosarsphenamine
dermatitis, effect of tobacco on, [Barksdale] *674; *675
jaundice after, due to intrahepatic biliary obstruction, [Hanger & Gutman] *263
nephritis or nephrosis in syphilitic from, 554
purpura haemorrhagica after, [Falconer] 413
—ab; 1131—ab
- ART: See Physicians, vocations
- ARTERIES: See also Aneurysm
Arteriosclerosis; Blood Vessels; Veins
carotid, ligation, effect on brain, [Cammerneyer] 1930—ab
Coronary: See also Angina Pectoris; Arterio-sclerosis; Thrombosis, coronary; Ventricular fibrillation
coronary blood flow, effect of distention of abdominal viscera, [Gilbert & others] *1962
coronary disease and military service, [Holzmann] 1233—ab
coronary disease and tobacco, [English & others] *1327
coronary disease, papaverine for, 1299
coronary disease, surgical treatment, [Fau-teux] 1056—ab
coronary occlusion (acute), rehabilitation after, [Master & Dack] *828; [Rapaport] 1390—C
coronary occlusion, pain (prodromal) in, [Blumenthal] 1305—ab
coronary occlusion painless, [Pollard] 245
—ab
Embolism: See Embolism
Fistula: See Fistula
ligation, effects on vasomotor system, [Le-riche] 1667—ab
none exempt from atherosclerosis, 2018
Pressure in: See Blood Pressure
Splenic: See Aneurysm
Thromboses: See Thrombosis
- ARTERIOSCLEROSIS, coronary, [Horn] 563
coronary, action of drugs on induced anoxemia, in, [Lery] 565—ab
injury, vascular syphills and cerebral thrombosis, 634
nephritis-lead poisoning-climate relationship; no arteries exempt from atherosclerosis, 2018
obliterations, treatment, [Wright] *893
ARTERITIS: See also Endarteritis; Periarthritis
clinical diagnosis of segmental occlusion in, [Palma] 892—ab
- ARTHRITIS: See also Gout; Rheumatism
acute suppurative, sulfanilamide for, [Lockwood] *1194
chronic, bacterial cultural studies, [Angerine] 2112—ab
chronic, predispose to fractures? 1823
chronic, roentgen therapy, [Smyth] 2209—ab
chronic, vitamin A requirements, [Hall] 889
—ab
etiology, estrogenic, 320
gonorrheal, sulfanilamide, mercurochrome, fever therapy, etc., for, [Culp] 160—ab
Hypertrophic: See Osteoarthritis
mono-articular and pauciarthritic, in children, [Green] 2023—ab
periarthritis, and para-arthritis producing no articular residues, [Hench] 2207—ab
Rheumatoid: See Arthritis, chronic
Treatment: See also Arthritis, acute suppurative; Arthritis, gonorrheal
treatment, estrogens, 320
- ARTHROTHESIS—Continued
treatment, gold, fatal, [Anderson & Palmer] *1627
treatment, local and regional anesthetic injections, [Steinbrocker] 2023—ab
treatment, physical therapy, especially at home, [Krusen] *605
treatment, sweet almond oil, 954
Tuberculous: See Knee
- ARTHUS? phenomena from histamine (T360) injection, [Greenbaum] *847
- ARTICLES: See Journals
- ARTIFICIAL Limbs: See Limbs
Pneumothorax: See Pneumothorax, Artificial (cross reference)
- ASCARIASIS, diagnosis: stool examination or intradermal tests, 1656
tropically acquired, and pregnancy, 1391
- ASCITES fluid protein in cirrhosis, [Mircoll] 1586—ab
- ASCOLI'S Method: See Malaria, treatment
- ASPHYXIA: See also Carbon Monoxide poisoning; Cyanosis; Suffocation
of newborn, [Morgenstern] 475—C
of newborn of diabetic mothers, [Sisson] *240
postmortem picture in 3 months old infant, 404
- ASPIRATION, bronchoscopic, in postoperative atelectasis, [Mousel] *899
Monaldi's: See Tuberculosis, Pulmonary
of sputum from adults; technic, [Auger] *1186
of stomach content in bronchopneumonia, [Irons & Apfelbach] *584
Pneumonia: See Pneumonia, lipoid
- ASPIRIN: See Acid, acetylsalicylic
- ASSOCIATED Health Foundation, Inc., medical expense indemnity plan, 2094—OS
- ASSOCIATION: See also American Association; American Medical Association; International Association; National Association; list of societies at end of letter S; Medical Abstracts at end of letter M
of American Medical Colleges, 1290
of aesthetists protest against nurse-anesthetists, England, 1818
of Life Insurance Medical Directors, 2097
from Medical Students, Wayne U. withdraws from, 1147—SS
of Military Surgeons of United States, 1112;
- ASTHENIA: See also Myasthenia; Neurasthenia
neurocirculatory, in soldiers, 537—E; (relation to hypothermia) [Reimann] *1606
- ASTHMA, after thyroidectomy, 1217
bronchitis after chronic upper respiratory infection, [Bivings] *1434
bronchostenosis complicating, [Prickman] 1831—ab
Canal Zone and, 1392
electrolyte and water exchange in; ptilressia affects, [Stoesser] 1922—ab
etiology, karaya and related gums in hal-setting fluid, etc., [Feinberg] 1491—ab
etiology of asthma occurring late in fall, 2262
etiology, offset printing spray in printers, 603
etiology, spores of rust and smut on grain, [Waldbott] 1401—ab
in pregnancy, 1743
nostrum, Crocker's, 1118—BI
pneumonia curative effect on, 1299
status asthmaticus, sulfanilamide for, [Well] 411—ab
treatment, aminophylline, [Carr] 1582—ab
treatment, eupaverine, a morphine derivative, [Dopfel] 239—ab; (correction) 470
treatment, inhalant allergens, in children, [Stoesser] 415—ab
treatment, parasympathetic-mimetic drugs, [Moll] 2031—ab
treatment, pollen orally, [Feinberg & others] *23
treatment, sulphyridine, 1299
- ATABRINE dehydrochloride, N.N.R., 1886
Treatment: See under Malaria
- ATAXIA, Locomotor: See Tabes Dorsalis
- ATELECTASIS: See Lungs collapse
- ATHEROSCLEROSIS: See Arteriosclerosis
- ATHLETICS: See also Exercise; Physical Education
after rheumatic fever, 152
bowling league, physicians', 1287
"doping" to improve performance, 1281—E
football deaths decline, 2013
golfers score, candy improves, [Michael] *286
swimming during pregnancy, 879
swimming, frontal sinusitis after, [Bucy & Haverfield] *983
- ATLAS AND AXIS, fracture of posterior arch of atlas, [Plaut] 73—C
- ATOM smashing: See Cyclotron
- ATROPHY: See also Adrenals; Fat; Pylonephritis, atrophic
muscular, examination and standards for Selective Service, 1559
unilateral of face, surgical treatment, [Kazanjian & Sturgis] *348
- ATROPINE prevents anginal pain after eating, [Gilbert & others] *1982
Treatment: See Heart block

AUDIOMETERS, progress report of Council's consultants, 854
AUDITORY Canal: See Ear
AUREX Hearing Aid, 45
AURICULAR FIBRILLATION, drug therapy, [Levy] *848
AURICULAR FLUTTER, drug therapy, [Levy] *849
AUSTRALIAN X disease, diagnosis (differential), [Toomey] *1985
AUTOINFECTION: See Strongyloidiasis
AUTOMATISM, ambulatory, or fugue, 478; (reply) [Mayer] 1218
AUTOMOBILES: See also Medicolegal Abstracts at end of letter M
accidents, head injury in, [Vorlis & others] *1769
accidents in rural area traversed by transcontinental highway, [Powers] *1521
accidents, Institute for Traffic Safety Training, 395
accidents, kidney injury in, [Sargent] *822
accidents, mental hygiene aspect, [Selling] *903
bumper fracture of tibial condyle, [Barr] *1683
driving (safe) at night: danger from unshielded lights on highways, [Gould] 632-C

DEATHS

A
Abbott, Maude Elizabeth Seymour, 1115
Abernethy, Claude Oliver, 873
Absher, Albert Allen, 795
Abt, Francis Joseph, 1654
Acker, William Barrett, 148
Adams, George Elbert, 399
Adams, Isaac Newton, 1117
Adams, Joseph Lawrence, 1565
Adams, Lemuel Payson, 2195
Adams, Numa Pompilius Garfield, 1035
Adamson, Frederick Richmond, 72
Agar, John Samuel, 1472
Alden, Charles Wallington, 1565
Alexander, James Moffatt, 949
Algulre, Alexander Ross, 1470
Allbritton, Lewis Gordon, 1820
Allen, Arthur West, 72
Allen, Richard, 72
Allen, Sherman Alonzo, 1654
Allen, Walter H., 1036
Allen, Walter Otis, 146
Allgood, Joseph Curry, 1737
Allingham, Arthur Westley, 874
Almon, William Bruce, 2100
Almsberg, Carl Lucas, 2296
Altman, John Thompson, 629
Alvey, Eugene Young, 2102
Alverson, Frank Lyn, 1904
Anderson, Frank Taylor, 2297
Andrews, Frederick Francis, 2195
Andrews, William Baird, 1214
Angeney, Ferdinand Glaser, 316
Anglin, George Washington, 1820
Anthony, Elsha Gordon, 1472
Appelman, John Sherman, 2196
Applewhite, Henry Learen, 2196
Aquaro, John, 2101
Archambault, La Salle, 1653
Archibald, Hal Sewell, 548
Armistead, Hal Sewell, 1565
Armstrong, Louis Woodruff, 795
Armstrong, Robert Burton, 795
Armstrong, Wilber Price, Sr., 630
Ashburn, Percy Moreau, 872
Askew, Pleasant H., Sr., 1293
Atkins, Benjamin Thomas, 71
Atkinson, James Meade, 1035
Atwell, Floyd Jerome, 1035
Auchmuty, John Edward, 630
Ault, Charles Alexander, 874
Austin, Frederick Da Costa, 1820
Austin, Victor Bodine, 1035
Ayres, Charles J., 2297

Bayles, Howard Alfred, 147
Baylis, George Benjamin, Jr., 1472
Beach, William A., 473
Beach, Charles Henry, 474
Beadles, Charles Henry, 2102
Beardsley, Jennie A., 1471
Beaton, Alexander Angus, 1388
Beckett, George Temple, 1565
Beckel, Marie Olivier, 473
Bedford, James Rosser, 2102
Beecher, Vasco Mortimer, Jr., 72
Beekman, John Bloomfield, 874
Begg, Alexander Swanson, 1470
Belmen, Charles E., 2102
Belding, George Henry, 2197
Bell, Claude, 2297
Bell, James Addison, 1117
Bell, John Henry, 233
Bemis, Royal Warren, 549
Benedict, Albert Clark, 2100
Bennet, Burnham Roswell, 147
Bennett, Clare Montgomery, 1389
Bennett, George Upton, 630
Bennett, John, Jr., 1905
Bennett, Joseph L., 474

EDUCATION, MEDICAL—Continued

anatomist in, 1938—SS
Annual Congress on, Feb. 1941, 1646—OS;
2010—OS
Course: See also Education, Medical, graduate
course at School of Aviation Medicine, 1025
course duration, *689
curriculum, *692; (Western Reserve changes)
1506—OS; (Michigan reduces number of
prescribed hours) 1943—SS; (Vermont
lengthens senior year) 1943—SS
examination (comprehensive) at Tennessee,
2238—SS
Flexner's influence on, 1888—E
graduate assemblies, clinical conferences and
intermittent study courses by states, (tables)
*721
graduate, assembly, (South Texas) 1816;
(Harrisburg, Pa.) 1816
graduate clinical conference, (Ga.) 789; (Mat-
toon, Illinois) 1561; 1899
graduate continuation courses, Minn., 1029
graduate continuation study for practitioners,
*709; (in proximity to their homes) *712;
(where there is ample clinical instruction
facilities) *714
graduate courses, (in obstetrics and pediatrics,
Ind.) 140; 1028; 1561; (in obstetrics, Okla.)
142; (in pediatrics, Chicago) 391; (Calif.)
467; (at New York U.) 790; (in obstetrics
and pediatrics, Neb.) 790; (counties spon-
sor, Ore.) 1112; (Ark.) 1287; (on derma-
tology, U. of Calif.) 1899 (on chest dis-
eases, N. Y.) 2012; (aviation medicine)
2095; (Toledo) 2097; (obstetrics, at Louisi-
ana State) 2191; (New York's state so-
ciety) 2192
graduate day in Toledo, 1467
graduate, foundations supporting, *720
graduate intramural, in obstetrics and pedi-
atrics, federal funds for, [Daily] *1436
graduate lectures, (Idaho) 65; (Argentina)
547; (Ohio) 1816
graduate programs, (in pediatrics and obstet-
rics, medical school as center for, in 6
states) 867; (Des Moines) 1110; (Mich.)
1210; (New York) 1384; (Summit County
Medical Society, O.) 1563
Graduate School: See Schools, Medical
graduate short courses, (tuberculosis, Ind.)
943
graduate study for Central American physici-
ans, 789
graduate study for Negro physicians, *720;
(Institute, District of Columbia) 1647
graduate training and experience, [Hunt] *1139
graduate training in criminal psychiatry,
Pennsylvania fellowship plan, 135—E; 544
history of, in U.S., [Hunt] *1137; 1888—E
in Germany, 224—OS
in U.S. and Canada, thirty-ninth annual
presentation of data on, *685
infiltration and integration in, 1504—SS
intensification in relation to Selective Service,
[various authors] 1204—ab
Lovell (A. Lawrence), president of Harvard
attitude on, 2333—S
number, August 31, *685
Postgraduate Work: See Education, Medical,
graduate
preclinical sciences, functions of 2236—SS
preliminary work required, *685; *688; (by
state boards) *689
premedical symposium at Duke, 1147—SS

EDUCATION, MEDICAL—Continued

summer clinic service for Creighton seniors,
1507—SS
teaching anatomy, chromatic brain specimens
for, [Darragh] *1630
teaching (full time) in clinical medicine, 1888
—E
teaching surgery, [Coughlin] *1936
under air raids, England, 1902
Washington Heights Health and Teaching
Center, 141
Wenckebach Clinic in Vienna, [Hyman] 2016
—C
EFCOLITE Corporation, fluorescent lighting
with argon, 239
EFFORT Syndrome: See Asthenia, neurocircu-
latory
ELECTRIC appliances (lamps, baker, heating
pad) for treating arthritis at home, [Kru-
sen] *606
cautery set, "Twin Control," "Single Con-
trol," and "Simplified Control," 1885
Current (Sinusoidal) Treatment: See Neu-
ralgia trigeminal
epilepsy, priority in inducing, [Furst] 1821—C
food grinder and stirrer, [Jones] *276
Induced Convulsions: See Mental Disease
treatment
Therapeutic Countershock: See Ventricular
Fibrillation
welding apparatus used on galvanized mate-
rial, metal fume fever from, 1119
ELECTROCARDIOGRAM: See Heart
ELECTRO-ENCEPHALOGRAPH: See Brain
ELECTROLYSIS of blood, Northcott's treat-
ment in hypertension, 1657
ELECTROLYTES and water exchange in asthma,
[Stoesser] 1922—ab
balance and mineral metabolism, 2106
changes in pulmonary tuberculosis, [Thorn]
2216—ab
ELECTRON microscope, research fellowship es-
tablished by RCA, 1031
ELECTROSURGERY: See Diathermy, surgical;
Electric cautery
ELECTROTHERMY: See Diathermy
ELEPHANTIASIS, surgical, or recurrent can-
cer of arms, 1477
EMBOLISM: See also Thrombosis
danger years later after recovery from endo-
carditis, 1218
etiology, abortifacient pastes, 221—E
peripheral arterial, [Koucky] 1916—ab
phenomenon with bacterial endocarditis, [Jef-
fries] 1664—ab
pulmonary, after injecting varicose veins,
[Harkins] 236—C; [Isaak] 632—C
pulmonary, and chronic saphenous phlebitis,
1121
pulmonary, and infarction, [Parsons-Smith]
1232—ab
pulmonary, and postoperative venous throm-
bosis, [Culp] 646—ab
pulmonary, and recurrent venous thrombosis,
322
pulmonary, and the weather, 222—E
pulmonary, antemortem recognition, [John-
son] 162—ab
pulmonary; ligation of iliac veins, 1298
pulmonary massive, fatal in appendicitis,
[Stamford & Sprong] *1243
pulmonary stimulating or complicating heart
disease, 2181—E; [White] 2309—ab
treatment, eupaverine (morphine derivative),
[Donnell] 259—ab; (correction) 470
EMBRYOMA of testis, [Mellon] 1582—ab

- EMERGENCY:** See also Diabetes Mellitus; First Aid
catastrophe unit on Queens General Hospital staff, 308

SUBJECT INDEX

2342

EUROPEAN WAR—Continued
medical supplies urgently needed by British,
229; 789; 1207; [Leinster] 1215—C; 1806;
2091

meningitis control in troops, England, 230;
[Cushing] 2031—ab
Physicians: See also European War, Ameri-
can physicians
physicians and their dependents, medical war
relief fund for temporary assistance, 1564
physicians' children, homes in Australia and
America for, 793; 947; 1102—E
physicians, compulsory service, England, 946
physicians' fitness for army service in case of,
Sweden, 69

physicians killed in, (O'Shaughnessy) 144; 1469
physicians, [Sargent] 891—ab
Royal Society of Medicine resolutions on pro-
tection of soldier, 626
Russo-Finnish War: See Russo-Finnish War

science and, 2099
tetanus prevention and treatment, 69
tuberculosis in recruits, detecting, 546
wound shock, Committee on Traumatic Shock
and Blood Transfusion report, 1564
wounded, American Doctors' War Relief Com-
mittee to aid, 790
wounded, blood transfusion donors wanted to
aid, New York, 789
wounded brought from France to England,
144

wounded, special surgical centers for, En-
gland, 870
Wounds: See also European War, armor
wounds, British government to pay civilians
for, 1033
wounds, hysterical contractures after, 1113
wounds of limbs, treatment, [Cohen] 1755
—ab

wounds, physical therapy for, 144
wounds, treatment, England, 870
wounds, use of sulfonamides by British Army,
1201; 2194
EUSTACHIAN TUBE block in compressed air
workers, helium-oxygen mixtures for,
[Crosson] 1312—ab

EVACUATION: See European War
EVACUATION: See also Medical Abstracts
EVIDENCE: See also letter M
at end of letter M
blood grouping tests in, regarding paternity;

- GLANDULAR Fever**: See Mononucleosis, Infectious
- Physiology and Therapy, Second Series**, (Council discusses) 133; (Introduction) [Fishbein] *1990; (relation of anterior pituitary to other endocrine glands) [Smith] *1991; (corticotropic, thyrotropic and parathyrotropic factors) [Collip] *2073; (anterior lobe of hypophysis in intermediary metabolism) [Thomson] *2169; (lactogenic and mammogenic hormones) [Riddle] *2276
- GLASS coverslips**, plastacele substitute for, [Norris] *1099
- potassium bitartrate crystals in grape jelly**, mistaken for, [Diamond] *682
- protection, in hospitals**, 1564
- GLASSES**: See also Eyes, examination; Vision, testing; Medicolegal Abstracts at end of letter M
- Industrial goggles, 552
- plano lens in safety spectacles, 1473—BI
- prescription for; effect of crossed cylinder, tinted lenses for motion picture operator, 77
- Yorgue Spectacle Company fraud**, 1473—BI
- GLAUCOMA**: See also Medicolegal Abstracts at end of letter M
- hereditary primary, [Stokes] 2311—ab
- prostagline effect on, 1122
- tension tolerance, [Gracie] *495
- GLOBULIN fraction, parenterally for in hemophilia**, [Conferences on Therapy] *214
- Immune Placental**: See Measles
- GLORIA Brand Pure Olive Oil**, 535
- Fluorim, 1906—BI**
- GLOSSITIS**: See Tongue inflammation
- GLOVES**, piliolin mitten used in applying wet dressings, [Stryker & Grindon] *121
- GLYCERYL TRINITRATE**, action on anoxemia in coronary sclerosis, [Levy] 563—ab
- GLYCOCOLL**, fails to increase muscular energy, [Maison] *1439
- GLYCOSURIA**, Renal: See Diabetes, Renal
- GLYCOTROPIC Factor**, [Thomson] *2171
- GOGGLES**: See also Goiter, Exophthalmic; Goiter: See also Goiter, Exophthalmic; Hyperthyroidism
- examination and standards for Selective Service, 1555; 1558
- GOITER, EXOPHTHALMIC**, [Reilly] 806—ab
- complications, diabetes, 151
- liver function in, [MacLagan] 2031—ab
- self-selected diets in, [Jones] *274
- thymus rests in, [Finochietto] 892—ab
- GOLD, effect in causing blood disorders**, [Conferences on Therapy] *383
- ferences on fatality from, [Anderson & Palmer] *1627
- Treatment: See Gold salt therapy; Malaria, therapeutic; Tuberculosis, Pulmonary**
- GOLF, American Medical Golfing Association**, 1897—OS
- candy or ketogenic lunch improves score; blood sugar in golfers, [Michael] *286
- GONADIN**, Council report, 1998
- GONADOGEN**, Council report, 1998
- GONADOTROPINS**, [Smith] *1992
- chorionic, side effects of, 799
- chorionic, treatment of menorrhagia and metrorrhagia, 75
- excretion in urine, stilbestrol effect on [Haam & others] *2267; *2269
- excretion: positive Friedman test in non-pregnant, [McCullagh] 1663—ab
- growth promoting hormones for use in girl dwarf aged 8, 1297
- serum of pregnant mares, Council report, 1998
- treatment of hirsuties, [Dorff] 248—ab
- treatment of hypogonadism in boy 17 years old, 2017
- treatment of undescended testes, [Rea] 490
- ab; [Zelson] 1752—ab
- treatment of undescended testes; later effect on surgery, [Eisenstaedt & others] *200
- treatment to stimulate ovulation, 320
- GONADS**: See also Ovary; Testis
- deficiency symptoms in women, estrogens for, [MacBryde & others] *440
- hypogonadism in boy 17 years old; and gonadotropins for, 2017
- pituitary relationship, [Smith] *1995
- GONOCOCCUS carrier**, [Carpenter] 247—ab
- GONORRHEA**: See also Venereal Disease
- Arthritis: See Arthritis
- control, (allotment of U.S. federal funds), 861—E; (Argentina) 1736
- examination and standards under Selective Service, 1552; 1557; (modified) 1776
- incidence in cities and states, U.S., 1901
- Ophthalmia: See Ophthalmia neonatorum
- prevention, chemical and mechanical, joint committee report, [Hazen & others] *1185
- salpingitis, 954
- septicemia and endocarditis, [Davis] 1131
- ab
- treatment, disulfanilamides, [Vest] 247—ab
- treatment, in women with and without sulfanilamide, [Brunet] 1312—ab
- treatment, sulfanilamide, in men, [Pelouze & others] *1630
- treatment, sulfapyridine, in women and children, [Moffett] 890—ab
- treatment, sulfapyridine orally, [Meler] 970
- ab
- treatment, sulfathiazole, [Culp] 1583—ab; [Cook] *2080; [Miescher] 2225—ab
- treatment, sulfathiazole and sulfapyridine orally, [Miescher] 892—ab
- vaginitis in young girls, estrogen treatment, effect on mucosa, [Finetti] 340—ab
- vulvovaginitis in children, [Mukherjee] 571
- ab
- vulvovaginitis, sulfonamide group for, [Carey] *926
- GOODY'S Headache Powder**, 631—BI
- GOUGEROT Syndrome**: chronic nodular phlebitis, 1122
- GOUT**, blood urate in relatives of persons with, [Talbot] 567—ab
- celebrated victims of, 1693—ab
- chalk, [Rosenberg] *1791
- in 17 year old girl, [Claborn] *38
- GRADUATE Courses**, etc.: See Education, Medical
- Schools: See Schools, Medical**
- GRADUATES**, at dawn of modern youth in medicine, [Hunt] *1137
- awarded B.S. in medicine, *700
- by states, *696
- number in U.S., 1905-1940, *699
- of Medical Field Service School, 1025
- of unapproved and foreign schools participation in medical preparedness, 2008
- sex distribution, *697
- students, 1939-1940, *698
- with baccalaureate degrees, *699
